"Antiseptic Methods" lays down certain guiding rules for the application of the general principle with which it is concerned. But the title does not suitably describe the scope of this little work, as it almost entirely deals with what we usually understand the "Aseptic" technique in operation, and during the dressing of surgical wounds.

The author, Mr. Upcott, draws attention to many apparently trivial but really essential details, which it is necessary to bear in mind to prevent wound infection. For instance, the precaution which should be taken in the preparation of the patient, the handling of sutures and basins during operations, and the subsequent removal of the stitches, are considered.

"Antiseptic methods" is written for dressers and surgical nurses. The beginner will certainly find it a very useful little book.

INTUSSUSCEPTION (*a*).

In this little book, the author, Mr. Clubbe, relates his experiences, which extend over a period of thirteen years, in the treatment of Intussusception. During this time he has dealt with what appears a very large number of cases (144).

The author is a strong advocate of a preliminary irrigation. He says: "I think injections of warm oil should be given in all cases, after the child is under the anæsthetic, even in cases of long standing, when we know that it is impossible to complete the reduction by these means. My reasons are these. It always reduces the intussusception to a certain extent, and in the best and gentlest possible way; in this way it lessens the shock of the coming operation, because less manipulation of the intestines is needed. It is specially useful in cases in which we find the intussusception in the rectum, because if we do not use it we may find some difficulty in getting our fingers below the tumour to commence the squeezing process." In fourteen cases reduction was brought about by this method alone. From his observations in 124 laparotomies for this condition the author asserts positively that adhesions between the invaginated portion of the gut do not exist, even when resection of the intestine is necessary. The irreducibility is due to the swelling and thickening of the intussusceptum.

This book is well worth perusal, especially by the young practitioner. Mr. Clubbe's style is simple and graphic, and he draws a very vivid picture of the symptoms of Intussusception, but his account of the differential diagnosis is scanty.

TRANSACTIONS OF THE ROYAL ACADEMY OF MEDICINE (*a*).

In this volume the first section, that of medicine, is the largest, and contains several papers of great interest. It opens with a paper in which the author explains the commonest functional heart murmur—*i.e.*, pulmonary systolic murmur—as being due to dilatation of the infundibulum of the right ventricle.

A long paper, entitled "Our Debt to Ireland in the Study of the Circulation," follows. In this is shown the enormous amount of work contributed to this branch of medicine by Irish physicians from the time of Graves and Stokes to the present day. Next are several papers which formed the subject-matter of a debate on the treatment of gastric ulcer. Of these, two are contributed by physicians, and two by surgeons. There is a paper, with bibliography, on the rare condition of movable spleen, founded on a case which simulated a movable kidney, with intermittent hydro or pyo-nephrosis. Another paper of interest is one on a case of myelogenous leuchæmia, in which the white blood corpuscles were reduced after three and a half months' treatment by X-rays from over 900,000 to 10,000, with reduction of a greatly enlarged spleen to normal size, and a corresponding improvement in the general symptoms.

In the surgical section the contribution on "Sphincteric Control of the Male Bladder and its Relation to Prostatectomy," will attract attention. The author comes to the conclusion, after performing various experiments on dogs, that probably in man the internal sphincter vesicæ is the important muscle, and not the compressor urethræ, as generally supposed. The idea

Pp. 167 and xiii. With eight illustrations and two plates of spectra. 1907. London: Bailliere, Tindall and Cox. Price 10s. 6d. net.

(*b*) "Antiseptic Methods; for Surgical Nurses and Dressers." By Harold Upcott, F.R.C.S. Pp. viii and 51. London: Bailliere, Tindall and Cox, 1907.

(*a*) "The Diagnosis and Treatment of Intussusception." By Charles P. B. Clubbe, Hon. Surgeon to the Prince Alfred Hospital, Sydney; Joint Lecturer in Clinical Surgery at the Sydney University. Pp. x and 92. Edinburgh and London: Young J. Pentland. 1907.

(*b*) "Transactions of the Royal Academy of Medicine in Ireland Vol. xxv. Dublin: John Falconer. 1907.

of these experiments was originated by a case under the author's care, in which, after perineal prostatectomy, the patient had voluntary control over micturition, which took place through a fistula in the perineum.

"Limits of Abdominal Operations" is the title of a paper concerning movable kidney, vermiform appendix, and gastroptosis. With most of what is said we are in accord, but we find it hard to reconcile the following two statements:—"I venture to think that one attack of appendicitis is sufficient to justify operation," and "I do not think operation advisable during a first attack, nor, indeed, during any attack, unless there is present some special indication." Surely it is better to remove the appendix at once, provided, of course, the case is seen sufficiently early—say, within the first 24 hours.

Then follow papers on a comparison of the treatment of enlarged prostate witnessed in some of the hospitals of Paris, Berlin, and London; on chronic pancreatitis successfully treated by draining the gall-bladder; on fractures of the shaft of the femur, advocating treatment by a modified Park Hill apparatus. The last paper in this section is one on intestinal obstruction, based on a series of 12 cases. In this the author speaks very strongly on the subject of high mortality—at least 40 per cent., "which disgraceful state of affairs," he says, "must be largely attributed to the pernicious habit of meddlesome medication and delay until the unfortunate patient is so profoundly poisoned by toxic absorption from his intestine, and exhausted to such an extent by pain and vomiting, that he is quite incapable of withstanding even the simplest surgical procedure." We fully endorse this statement.

This section concludes with brief abstracts of numerous cases and specimens shown at the meetings. We are glad to note that several of the contributions in this volume are by physicians not resident in Dublin, showing that the Society is not merely of local interest. Then follow the sections of obstetrics, pathology, State medicine, anatomy, and physiology.

DISEASE IN CHILDREN. (*a*)

No one who is acquainted with Dr. Sutherland's skill as a diagnostician and teacher can fail to open this book with eager expectancy. We look for thoroughness in anything that he puts his name to, and in this case we are not disappointed. This is certainly one of the best of the Oxford medical publications. It is written in a somewhat authoritative style, but there is throughout much that is convincing. We are pleased to observe that the author does not recommend arsenic in the treatment of chorea. With small doses he has never got good results, while large doses, he says truly, are not by any means free from risk.

In connection with congenital pyloric stenosis we observe that the author still ventures to recommend operation, especially in those cases where medical treatment has failed. In this respect he follows the teaching of most authorities at the present time. He has a good deal to say on the subject of incontinence of urine, and he mentions adenoids and enlarged tonsils as associated causal conditions. This, however, is not our experience, and we have frequently found the condition actually rendered worse by operation for these growths. He prefers atropine to belladonna, as the former is more active. This is Holt's teaching, and we believe it is to be highly commended. To be of any value, however, it must be given in full doses.

Vulvo-vaginitis in its commonest form, he says, is due to want of cleanliness. In other words it is simple and not gonorrhoeal in nature. We are glad to find that this is the opinion of a practical observer as Dr. Sutherland undoubtedly is, for we so often hear it taught in these days that the majority of these cases in children are really due to the gonococcus. In fact, it will be found that the author's teaching is uniformly sound and common-sense in principle. The book is free from padding and unnecessary verbiage. All the commoner diseases of infancy and childhood are included. An appendix of useful prescriptions completes this thoroughly practical little work. We heartily recommend it as a guide to junior practitioners and to those who for some reason or other have not made a special study of children's diseases during their medical curriculum. A study of this volume will afford the reader many valuable hints which he will find of very great service in practice.

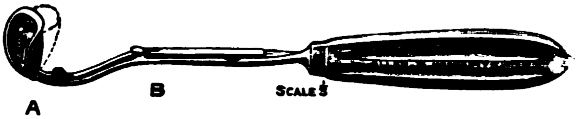
THE MODERN TREATMENT OF PULMONARY CONSUMPTION (*a*).

DR. LATHAM'S book has now become one of the standard works on the subject with which it treats, and it is so well known that a brief notice is all that is necessary of the third edition. The most important change in the present edition is the insertion of a section on the value of the opsonic index in diagnosis and treatment, and the use of the new tuberculin. It will, we are sure, be a great satisfaction to many clinicians to learn from Dr. Latham that in his experience the treatment by tuberculin can be quite as readily carried out and as safely controlled by clinical evidence as by the opsonic investigation. Were we dependent on the opsonic investigation for the use of tuberculin, its use would be very much limited—among the poor, at all events, where it is most wanted. We sincerely trust that the book will have a wide circulation among the general practitioners of this country, where all forms of tuberculosis are so common.

NEW MEDICAL AND SURGICAL APPLIANCES.

A NEW POST-NASAL CURETTE.

THE use of a curette for the removal of adenoids, in preference to the post-nasal forceps, has now become an established method. It was Delstanche who first invented an ingenious hinged and toothed cage to Gottstein's curette. The post-nasal curette generally used has a straight shaft from the catch to the handle, and when introduced behind the soft palate and swept downwards and backwards, the shaft of necessity is elevated, the result being that considerable bruising of the uvula and soft palate is caused. In the instrument devised by Mr. William Lloyd, F.R.C.S., and manufactured by Messrs. Allen and Hanburys, Ltd., the shank is curved from A to B, with the result that in the large number of cases in which the inventor has used it, traumatic inflammation, etc., is avoided.



NEW "TABLOID" SLIPPERY ELM.

MUCILAGE of slippery elm is largely used as a demulcent and astringent sedative. Alone, or combined with phenol, it is employed locally in pharyngitis and other throat affections, and internally in diarrhoea and dysentery. The mucilage is also stated to have a nutritive value. In tabloid form slippery elm presents a convenient means of administration. Each represents 5 gr. (0.324 gm.) of the mucilage, and one may be slowly dissolved in the mouth or swallowed whole with water as required.

CARBOLIC ACID AND SLIPPERY ELM.

Each tabloid contains carbolic acid ½ gr. (0.032 gm.). One may be slowly dissolved in the mouth, or one to two swallowed whole with water twice or thrice daily after food. Both the foregoing tabloids are issued in bottles by Messrs. Burroughs, Wellcome and Co.

MEDICAL NEWS IN BRIEF

Death Under Nitrous-Oxide Gas.

MR. WALTER SCHROEDER held an inquest at Holborn on November 9th on Louisa Allen, 30, who died at a dentist's.

The husband, Alexander Allen, said his wife had suffered from neuralgia for some time, and had been under medical treatment for the last three months. She went to the Welbeck Street Dispensary for Epilepsy and Paralysis, and she was advised to consult Mr. Cox-Moore regarding her teeth. She went to him, and he extracted four of her teeth. She left home on Thursday seemingly in good spirits, in order to go and have more teeth taken out. Later in the day witness was summoned by telegram, and on arriving at the dentist's he found that his wife had died under the operation.

Mr. Edward Cox-Moore said he had practised as a dental surgeon for twenty-five years. Mrs. Allen went to him as a Hospital Saturday Fund patient, and had four teeth extracted under a nitrous-oxide gas anæsthetic. When she came on the second occasion he administered a moderate dose of gas nitrous-oxide, using a face apparatus which was regarded as perfectly safe. The gas took effect, and he took out the teeth that had been selected, and found the woman in a normal state and regaining consciousness. About two minutes later she lurched forward and died. He believed that the patient was not under the influence of the anæsthetic when she died, although he would not positively state that she had recovered consciousness. He had for the last seven or eight years given an anæsthetic to about 1,500 persons annually, without mishap.

Witness's statement was corroborated by John L. Burden, who assisted him.

The evidence of Dr. W. Harper, Bloomsbury Square, was to the effect that death was due to syncope whilst suffering from fatty degeneration of the heart and whilst under the influence of an anæsthetic.

A verdict of "Death from misadventure" was returned.

Spreading Scarlet Fever.

WILLIAM RANCE, a fried fish dealer, of Leyton, was summoned at Stratford for exposing a child while suffering from scarlet fever without proper precautions.

Dr. F. J. Taylor, Medical Officer of Health for Leyton, prosecuted, and said that on October 16th he examined defendant's child, certified it to be suffering from scarlet fever, and gave directions for isolation. On the 17th Mr. Miller, sanitary inspector, found the child isolated, but on the 23rd the boy was seen running about with other children. The defendant said the child was a great trouble, and he had no control over him. On October 25th, when the inspector called, the boy was seen without a coat and with wet hands. He said he had been washing potatoes. On October 29 the boy's mother said he was out of doors—she could not keep him in—but the next day isolation had again been resorted to. On the 31st Mr. Miller saw the boy in High Road, Leyton, wheeling his sister in a cart.

Dr. Taylor added that there was a great deal of scarlet fever about, and the ignorance of people created a difficulty, but when persistent obstinacy was added to it there was more difficulty still.

The defendant said at first he did not know the child was suffering from scarlet fever, and when he was told his wife did her best to keep him upstairs, but he would not stay.

The Bench said they regarded it as a serious matter, and imposed a fine of 20s. and costs.

Dublin Hospital Sunday Fund.

THE annual collection for the Dublin Hospital Sunday Fund took place on Sunday last, and will, we trust, result in a large addition to this most valued fund. The fund assists no fewer than 15 institutions, which provide 1,543 beds for the sick poor, and receive annually 16,000 patients, in addition to the many treated at outlying dispensaries, and about 29,000 accident cases. Since 1897 the fund has distributed to the hospitals no less than £126,775 15s. 9d. During the past two or three years the collections have been smaller in comparison with previous years. The Earl of Meath, President of the fund, has made an appeal in its behalf which we hope will re-establish the fund on its old basis, and thus further a most necessary work. Additional contributions may also be sent to the Royal Bank of Ireland, Dublin, or to the Treasurer, Mr. Joseph T. Pim, of 22, William Street, Dublin.

Session of the General Medical Council.

WE are requested to announce that the autumn meeting of the General Council of Medical Education and Registration will commence on Tuesday, the 26th inst. The President, Dr. Donald MacAlister, will take the chair at 2 p.m.

PASS LISTS.

Conjoint Examinations in Ireland.

THE following candidates have passed the First Professional Examination of the Royal College of Physicians and the Royal College of Surgeons:—

U. L. Bourke, F. E. Fitzmaurice, J. M. Gilmore, C. W. Joynt, J. Kirker, C. J. Kelly, A. G. J. MacIlwaine, B. Malaher, B. Murphy, D. McDevitt, B. Neary, A. J. Neilan, J. M. K. O'Byrne, J. H. Rishworth, C. Roche, G. Wilson, G. Young.

The following have passed the Second Professional Examination:—J. J. Barry, F. J. Graham, P. Grace, R. H. Hodges, W. H. Murray, M. O'Brien, H. C. Smyth, J. P. Shorten.

The following have passed the Third Professional Examination:—S. J. Barry, A. J. Bennett, G. E. Beggs, H. F. Blood, T. C. Casey, Miss C. Daniell, J. C. L. Day, E. C. Deane, E. Dundon, H. Hunt, F. M. Harvey, S. W. Hudson, L. C. Johnston, J. O'L. Murray, J. Menton, M. C. O'Hara, J. C. O'Connell, R. Power, W. F. Russell, C. D. K. Seaver, I. Scher, H. B. Sherlock.

The following have passed the Final Examination:—C. W. Green (Honours), M. D. Healy, M.D., Denver Univ. (Honours), J. McNamara (Honours), H. C. Carden, W. J. Connolly, A. Curry, B. Foley, G. A. Francis, E. H. F. Gilligan, G. J. M. Martin, E. Montgomery, W. St. L. Moorhead, P. J. Murray, C. McQueen, M. H. O'Sullivan, J. T. Rearden, G. F. Shepherd, P. D. Walsh.

The following candidates have passed the Diploma in Public Health, November, 1907: Major J. W. Bullen, M.D., R.U.I., R.A.M.C.; E. J. Day, M.D., Univ. Durham; F. C. Drew, M.B., Univ. Edin.; Capt. D. P. Johnstone, L.R.C.P. and S. Edin.; G. A. Moorhead, F.R.C.S.I.

Apothecaries' Hall of Ireland.

AT examinations recently held, the following candidates passed in the subjects indicated:—John W. Harvey, Physics; J. Stewart, Physiology; John Clarke and J. Hargraves Robinson, Pathology; Alexander Silbermaine and John Clarke, Hygiene; Major Moody, Alexander Silbermaine, and John Clarke, Medical Jurisprudence; Alexander Silbermaine, Materia Medica (Honours); John Clarke and Alexander Silbermaine, Pharmacy; J. M. Downer, Khaja Moinuddin, and N. Murphy, Surgery; S. V. O'Connor and J. Hargraves Robinson, Medicine; J. M. Downer and J. Hargraves Robinson, Midwifery (Honours).

The Diploma of the Apothecaries' Hall was granted to the following candidates, entitling them to practice Medicine, Surgery, Midwifery, and Pharmacy: J. M. Downer, Khaja Moinuddin, and N. Murphy.

Faculty of Physicians and Surgeons of Glasgow.

AT a meeting of the Fellows of the Faculty last week, the following office-bearers were appointed for the following year, viz.:—Dr. John Glaister, President; Mr. D. N. Knox, Visitor. Councillors: The President, ex-officio; The Visitor, ex-officio; The Treasurer, ex-officio; Dr. J. Lindsay Steven, as Representative to the General Medical Council; Dr. Robert Perry, Dr. Neil Carmichael, Mr. H. E. Clark, Dr. Ebenezer Duncan, Mr. J. Walker Downie, Dr. John Barlow; Dr. W. G. Dun, Treasurer; Dr. J. Lindsay Steven, Honorary Librarian. Board of Examiners for the License: William H. Hill, LL.D., Clerk; Alexander Duncan, B.A., LL.D., Secretary and Librarian; Walter Hurst, Assistant Secretary and Librarian; William Matthews, Officer.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Recurrence of Retroperitoneal Lipoma.—Johnstone (*Brit. Med. Journ.*, Oct. 12th, 1907) reports a case in which he removed a retroperitoneal lipoma weighing 21 lbs. in 1905. It was situated in intimate relation to the right kidney and ureter, and the tumour was shelled out of its bed apparently completely. The patient remained perfectly free from disease for about two years, but then commenced to suffer from stomach troubles. On re-admission to hospital the abdomen was found to be distended and filled with lobulated tumours. The individual masses were firm in consistence, and one in particular was so hard that malignant recurrence was feared. On opening the abdomen the tumour was found to consist of a number of lobules varying in size from that of a goose egg up to that of a Rugby football. They were more or less pedunculated, and only united at their common site of origin, which was in the right flank in angle between the outer border of the kidney and the iliac crest. All the masses were removed, the perirenal fat being completely cleared away, leaving the quadratus lumborum bare. The peritoneum was sutured over the denuded muscles, and the abdomen closed. The tumour masses weighed altogether 12½ lbs., were pinkish white in colour when fresh, and the microscope showed typical lipomatous tissue, with no trace of malignancy. The patient had an uneventful convalescence. S.

Anastomosis Between the Common Bile Duct and the Duodenum for Obstructive Jaundice.—Fullerton (*Brit. Med. Journ.*, Oct. 26th, 1907) reports the following case:—The patient, a male, æt. 66, had no history of any illness whatever since childhood. He was quite well until three weeks before admission into hospital, when the patient's friends noticed that he was jaundiced, and he commenced then to lose flesh. There was no pain. The liver was enlarged, and the gall-bladder was distended almost to the umbilicus. The probable cause of the condition was thought to be carcinoma of the head of the pancreas or of the common bile duct near its termination. No tumour except the distended gall-bladder could be felt. On opening the abdomen the gall-bladder was found to be larger than a goose's egg, and contained three small stones. None were found in the cystic duct. When the liver was drawn up, a hugely dilated common bile duct, about as large as a piece of small intestine, was found. On opening the duct a quantity of glairy fluid with no trace of bile in it escaped. The finger could be introduced into the duct and passed up into the cavities in the liver, corresponding with the hepatic ducts. With some difficulty the common bile duct was anastomosed to the first part of the duodenum with a Murphy's button. The gall-bladder was stitched to the peritoneum and transversalis fascia, and drained. Three weeks after the operation the Murphy's button was passed, and about the same time the gall-bladder fistula closed. On examination five months after the operation the patient was found to be in good health and had put on flesh. S.

Cholecystectomy: The Indications and Contra-Indications for its Performance.—Mayo Robson (*Brit. Med. Journ.*, Oct. 26th, 1907) is strongly of the opinion that the gall-bladder should not be treated as a dangerous organ in the summary fashion in which we now deal with the appendix. The gall-bladder adds mucous to the bile, and thus makes the latter less irritant. If the reservoir function of the gall-bladder is lost, it leads to dilatation of the common bile ducts and the hepatic ducts and back pressure on the secreting part of the liver. Mayo Robson has also found that at times this condition leads to interstitial pancreatitis. The author has removed the gall-bladder 94 times in nearly 1,000 operations on the biliary passages. The indications for cholecystectomy are:—(1) In cancer or other new growth of the gall-bladder. (2) In contracted and useless gall-bladder, the result of repeated attacks of cholecystitis. (3) In dilated and hypertrophied gall-bladder resulting from obstruction of the cystic duct. (4) In phlegmonous or gangrenous cholecystitis. (5) In empyema of the gall-bladder. (6) In mucous fistula of the gall-bladder, the result of stricture or other obstruction of the cystic duct. (7) In gunshot or other serious injuries of the gall-bladder or cystic duct. Cholecystectomy is contra-indicated in all cases where the surgeon cannot be certain that the deeper bile passages are free from obstruction unless at the same time the cystic or common bile duct be short-circuited into the intestine. S.

Rupture of the Liver: Operation—Death.—Haubold (*Med. Record*, Oct. 26th, 1907) describes the case of a man, æt. 29, who fell about eight feet and struck the lower portion of the right chest against a pile of lumber. This caused him considerable pain, but he walked a long distance home without any assistance. During the night he vomited the contents of the stomach, and the pain in the side increased. On admission to the hospital next morning a linear contusion was found extending from the anterior portion of the seventh rib to the tenth rib at the posterior axillary line. Temperature 99 deg. in rectum, pulse 88. Abdomen moderately distended. No broken ribs. The face was pinched, but there was no pallor, restlessness, or thirst. Fifty hours after injury the temperature was 99, pulse 90. There were no symptoms of progressive hæmorrhage, and the man's condition was considered to be improved. Yet the history and the anxious expression of the face, and the distended and rigid condition of the abdomen, led to the belief that the liver was ruptured, and justified laparotomy. On opening the abdomen, it was found full of dark fluid blood. An irregular rupture of the liver surface three inches in length was found, situated low down in the right lobe, and so far posteriorly as to preclude repair by sewing or cautery. There was some oozing from the wound, but not so active as to cause immediate alarm. The abdomen was flushed out with hot saline, a Mikulicz tampon was passed down to and into the wound, and gauze was carefully packed into it. This seemed to control the bleeding. The patient went off the table in a moderate state of shock. Pulse 98, respirations 32. The tampon seemed to interfere with respirations to a considerable extent. The pulse, temperature, and respiration continued to rise, and the patient died eleven hours after operation. At death the pulse was 120, respirations 45, and temperature 105 deg. The case presented some unique features. There was at no time any evidence of shock, nor at any time were there symptoms generally regarded as indicative of progressive internal hæmorrhage. The persistent rise of temperature after operation would argue strongly against the assumption that bleeding had not been arrested. Hyperpyrexia at death is usually regarded as due to exaggerated or disturbed metabolism, and the author considers that perhaps it can be explained in this case by the disturbance of the peculiar function the liver has as an internal secreting organ. S.

Mobility of the Kidneys.—H. Mackenzie (*Lancet*, Oct. 16th, 1907) discusses the cause and frequency of this condition. Of 113 cases operated on by fixing the kidney, 80 were completely successful, 17 were partially successful, 13 were failures, and 3 died as the result of the operation. The author believes that movable kidney is undoubtedly a very common condition, in the female subject especially so; that in the

great majority of cases it produces no symptoms, and that it requires no treatment when local symptoms are absent. When local symptoms are present, a fair trial should first be made with non-operative methods of treatment. Only when such methods have failed to relieve, or when there is good reason to believe that the kidney may be the seat of disease, should recourse be had to operation. The operation should consist in exposing and thoroughly examining the kidney for any traces of disease, and, should none be found, fixing the kidney in a thorough manner back into the loin.
G.

Tumours of the Bladder.—Kolischer (*Jour. Am. Ass.*, July, 1907) gives his experience in the treatment of vesical tumours. He holds that all cases of benign tumours of the bladder should be approached from within, all malignant tumours from the outside of the viscus. In all malignant cases in which the loss of substance is not too great, the bladder should be closed completely by sutures after the removal of the tumour. In cases of malignant growths, the incision into the bladder should be made in accordance with the location of the growth, as defined by a previous cystoscopic examination. The permanent catheter should be absolutely abolished after such operations on the bladder. It causes much irritation, and does no good. It is far better to pass a catheter at regular intervals into the bladder than to leave one tied in. Gas anæsthesia should be employed exclusively. A constant cystoscopic surveillance should be maintained over any bladder that has ever been operated on for tumour. In cases where the tumour is malignant and too far advanced to permit of any radical treatment, the bladder may be opened and the growth freely cauterised with an actual cautery. This, however, seldom gives more than temporary relief. The method of treatment which furnishes more satisfactory results, consists in establishing permanent kidney fistulæ, and thus preventing any urine passing into the bladder.
G.

A Method of Cystopexy for Cystocele.—L. Smith describes (*Montreal Med. Jour.*, April, 1907) an operation for this condition, which is easy to perform, and in his hands has given most successful results. The abdomen is opened just above the symphysis pubis, the bladder is seen lying low down in the pelvis, and must be gently grasped by a bullet forceps, and drawn up as high as it will go, without employing any force. Both the peritoneal surfaces on the bladder and on the anterior abdominal wall are scarified or criss-crossed with a needle, until there is a slight oozing of blood. A curved needle is then passed through the abdominal wall, including all the layers except the skin and fat. It is then passed under the scarified surface on the bladder wall, care being taken only to include the peritoneal and muscular coats, and not to injure the mucous coat. The needle is again passed through the abdominal wall at the other side of the raw peritoneal surface. Three similar sutures are passed, each of medium chromicised catgut, which should last for about a month without absorbing. No precautions are necessary with regard to emptying the bladder. As a rule the patient can do this without the help of a catheter from the very first.
G.

Doctor Dies of Cocaine.

Dr. John Ernest Cook, aged thirty-eight, unmarried, and practising at Darnley Road, Hackney, was found dead in his dining-room on November 6th, and the coroner's inquest, held on Saturday, showed that he had died from cocaine poisoning.

Witnesses said that Dr. Cook had been doing well in his practice, but he suffered much from neuralgia, rheumatism, insomnia, and other trying complaints, and twelve months ago he had to be treated by another medical man for an excessive dose of cocaine. He had never spoken of suicide, and left no written statement.

When found he was lying on the hearthrug beside an overturned chair, and the gas lights were burning.

After hearing the evidence, the jury found "Death from misadventure."

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

Sidney Appleton (London).
The Diseases of Infancy and Childhood. By L. Emmett Holt, M.D., Sc.D., etc. Illustrated. Fourth Edition, revised and enlarged. Pp. 1,171. Price 25s. net.

Bailliere, Tindall and Cox (London).
Cancer. By G. Sherman Bigg, F.R.C.S.Edin., M.R.C.S.Eng., L.S.A. Pp. 85. Price 3s. 6d. net.

John Bale, Sons and Danielsson, Ltd. (London).
Syphilis in the Army. By Major H. C. French, R.A.M.C. Pp. 126. Price 6s. net.

Adam and Charles Black (London).
Black's Medical Dictionary. Edited by John D. Comrie, M.A., B.Sc., M.B., L.R.C.P. Third Edition. Illustrated. Pp. 856. Price 7s. 6d. net.

Church of England Temperance Society (London).
Side-lights on Alcohol and its Action on the Human Organism. By "Medicus Abstinens." Pp. 185. Price 2s. 6d net.

Churchill J. and A. (London).
The Operations of Surgery. By W. H. A. Jacobson, M.Ch. Oxon., F.R.C.S., and R. P. Rowlands, M.S.Lond., F.R.C.S. Fifth Edition. Volumes I and II. Pp. 2,055. Price 42s. net.
The Book of Prescriptions (Beasley), with an Index of Diseases and Remedies. Rewritten by E. W. Lucas, F.I.C., F.C.S., with an Introduction by Arthur Sullivan, M.A., M.D., L.R.C.P. Ninth Edition. Pp. 366. Price 6s. net.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

DAKHYL v. LABOUCHERE.

A DISCLAIMER.

To the Editor of The Medical Press and Circular.

Sir.—The name of "Dr. Cheetham" in association with the Drouet Institute having cropped up and been mentioned to me by patients, I beg to say, as the only medico of that name in practice in London, that I am not, and never have been, connected in any way with any of the parties, and send this disclaimer to remove what impression my patients and the general public have received against my strictly ethical career for 16 years at this address. S. W. Cheetham.

233 Romford Road, Forest Gate, E.

Christian Science denies the existence of illness, but the report in the "Christian Science Sentinel" of a meeting at Dixon, Illinois, is headed Dixon, Ill.—*Star.*

POISONOUS ENAMEL IN RECEPTACLES FOR FOOD.

A special report has been issued by the Home Office on the coating of metal with lead or a mixture of lead and tin. It deals with the effects of employment in the enamelling of metals and in tinning processes. It recommends that the addition of lead to the covering mixture in the tinning of iron and metal hollow-ware should be prohibited. Prohibition meets among other things the dangers such as that common tinned utensils may constitute a danger to the consumer. After treating of precautions, the application of exhaust ventilation, and other points, the report submits a draft of proposed regulations which define the duties of both employers and persons employed.

R. A.—We shall be happy to publish a letter on the subject if you will write one and keep it within moderate bounds as to the length and tone. We can only take general responsibility under the circumstances, and give you the opportunity of replying if you think your position has not been fairly represented.

M. D. Black.—We are sorry not to be able to do as you wish, but you will admit surely that it is reasonable. We really cannot write to the gentleman in question and remonstrate, however heinous his conduct. It may be a matter for the General Medical Council, the Medical Defence Union or some such body; but why for us?

Mr. H. Morton.—The populations of the five cities referred to, a given officially by the Registrar-General, are:—Birmingham, 553,155; Leeds, 470,268; Manchester, 643,148; Liverpool, 746,144; Sheffield; 455,553. Of these, during the month of October, Liverpool had the, highest death-rate, closely pressed by Sheffield.

LAST WORDS OF MEDICAL MEN.

"S. W." sends to the *Westminster Gazette*, on "The Last Words of Medical Men," the following historical instance of a patient's last words to his medical man:—M. de Calonne, one of the last Ministers of Finance of Louis XVI., in his last illness asked for a pencil, and wrote down the following words for the benefit of the doctor who attended him: "Docteur, vous m'avez assassiné! Si vous êtes un honnête homme, renonçez, à la médecine pour jamais."

Meetings of the Societies, Lectures, &c.

Wednesday, November 13th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. M. White: Clinique. (Surgical.) 5.15 p.m.: Lecture: Mr. D. Armour: Head Injuries.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks). 4.30 p.m.: Demonstration:—Mr. Brooks: Selected Eye Cases.

Thursday, November 14th.

Royal Society of Medicine (Obstetrical and Gynæcological Section) (20 Hanover Square, W.).—7.45 p.m.: Specimens will be shown by the President (Dr. H. Spencer), Mr. A. Doran, Dr. Fairbairn, Dr. Macnaughton-Jones, and Dr. C. H. Roberts. Paper:—Dr. T. Wilson: Pubiotomy (with illustrative cases).

United Services Medical Society (Royal Army Medical College, Millbank, S.W.).—8.30 p.m.: Paper:—Major W. S. Harrison, R.A.M.C.: Enteric Fever in War.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. F. B. Jessett: Carcinoma of the Uterus, the Importance of Early Diagnosis; Symptoms and Treatment.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappell). 5 p.m.: Demonstration at the Mount Vernon Hospital, Hampstead, N.W.:—Dr. J. E. Squire: Selected Chest Cases.

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Tuberculosis of the Skin: I., Lupus Vulgaris; II., Tuberculosis Verrucosa Cutis; III., Scrofuloderma.

Hospital for Sick Children (Gt. Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Colman: Splenic Enlargement.

Friday, November 15th.

Society for the Study of Disease in Children (11 Chandos Street, Cavendish Square, W.).—4.30 p.m.: Cases will be shown by Dr. Clutterbuck, Dr. G. Carpenter, Dr. F. J. Poynton, Mr. J. R. Howard, Mr. R. Warren, and others. Paper:—Dr. G. H. Lock: Case of Rheumatic Hyperpyrexia in a Child aged Six Years.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Dr. J. Horne: Clinique. (Throat.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Outpatient (Mr. H. Evans). 2.30 p.m.: Surgical operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Great Northern Central Hospital (Holloway Road, N.).—3 p.m. Clinical Lecture:—Mr. G. Coats: Some Points in the Diagnosis and Treatment of Conjunctivitis.

Central London Throat and Ear Hospital (Gray's Inn Road, W.C.).—3.45 p.m.: Demonstration:—Dr. D. McKenzie: Thyroid and Cervical Region.

Appointments.

Luard, H. B., M.B., B.C., D.P.H.Cantab., Certifying Surgeon under the Factory and Workshop Act for the Osmotherley District of the county of York.

Lupton, Harry, M.R.C.S., L.R.C.P.Lond., Consulting Surgeon to the Stratford-on-Avon Hospital.

Macdonald, Gilbert Reginald, L.R.C.P., L.R.C.S.Irel., Medical Officer for the Fourth District by the Wellington (Somerset) Board of Guardians.

Renton, J. Mill, M.B., Ch.B.Glasg., Extra Dispensary Surgeon to the Western Infirmary, Glasgow.

Roy, J. Allan C., M.B., Ch.B.,Vict., Assistant Medical Officer at the Royal Asylum, Cheadle.

Vacancies.

Ayr District Lunacy Board.—Medical Superintendent. Salary, £500 per annum, with house (unfurnished), fuel, light, water, vegetables, and washing. Applications to Mr. J. E. Shaw, County Buildings, Ayr.

Glasgow District Asylum, Woodilee, Lenzie.—Junior Assistant Medical Officer. Salary, £125 per annum, board, lodging, washing, etc. Applications to Dr. Marr, Medical Superintendent.

Haverfordwest Rural District Council.—Medical Officer of Health. Salary, £150 per annum, inclusive of all expenses. Applications to John E. H. Rogers, Clerk, 7, Dew Street, Haverfordwest.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary, £160. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26, Mosley Street, Newcastle-on-Tyne.

Peckham House Asylum, London, S.E.—Junior Assistant Medical Officer. Salary, £150 per annum. Applications to the Resident Licensee.

Parish of St. Giles, Camberwell.—Assistant Medical Officer for their Infirmary, Brunswick Square, Camberwell. Salary, £140 per annum, with apartments, board, and washing. Applications to Charles S. Stevens, Clerk to the Guardians, Guardians' Offices, 29, Peckham Road, S.E.

Births.

Corner.—On Nov. 9th, at 37, Harley Street, London, W., the wife of Edwd. M. Corner, M.C., F.R.C.S., of a daughter.

Simson.—On Nov. 8th, at 35, Cheyne Court, Chelsea, the wife of Captain Harold Simson, R.A.M.C., of a son.

Speirs.—On Nov. 7th, at The Cedars, Diss, Norfolk, to Dr. and Mrs. H. Meredith Speirs—a daughter.

White.—On Nov. 2nd, at Kasauli, Punjab, to the wife of Capt. F Norman White, M.D., I.M.S.—a son. (By cable).

Marriages.

Denny—Hood.—On Nov. 7th, at St. Anselm's Church, Davies Street, Edward Henry Marland, second son of the late Edward Maynard Denny, of 11, Bryanston Square, London, to Barbara Mary, second daughter of Donald W. C. Hood, C.V.O., M.D., F.R.C.P., of 43, Green Street, Park Lane, London.

Turner—Keysell.—On Nov. 2nd, at the Parish Church, Ware, Olivier Polhill, M.R.C.S., etc., third son of R. Drysdale Turner, of San Remo, to Amy Charlotte (Cissie), only daughter of the late Francis P. Keysell, of Grove House, Cheshunt, and Mrs. Keysell, Ware, Herts.

NOTES AND COMMENTS.

Property in Museum Specimens.

A LAWSUIT in Sydney has raised an interesting and discomforting question for pathologists. It is a well-known maxim of the British law that there is no property in a corpse, though as a matter of fact public opinion, which is stronger than any law, would not for a moment allow anyone but the relatives of a deceased person to have possession of his body. Now, if there is no property in a thing, presumably there can be no property in, and consequently no theft of, its parts. There is then no harm in the removal of diseased portions of a body for museum specimens, and equally—and this is the discriminating point—there is no harm in anyone walking off with these specimens whenever they choose. Does a tumour become property when it is taken from a dead body and placed in a jar of formalin? Apparently not, for in the case in question the plaintiff sued the police for detaining a jar containing a dicephalous child, which his father had bought twenty-two years previously for £27, and the judge non-suited him on the ground that there could be no property in a corpse. It is not pleasant to think than an enterprising stranger might remove John Hunter's Collection from the College of Surgeons' Museum, and that all the police in Bow Street could not raise a finger to stop him. But it might be possible to prosecute a scientific enthusiast of such a kind for stealing the glass jars and spirit, and even for damage to the jars. So that without mentioning the specimen within, possession might be recovered of the jar, from which the specimen could not be removed without causing malicious injury.

Homœopaths Again.

OUR esteemed contemporary, the *British Homœopathic Review*, is, we are sorry to say, pained by some comments of ours on the proceedings of the homœopathic meeting at Harrogate last summer. The ideas expressed at that gathering, though well known, it appears, to homœopaths for nearly a century, are "too novel and revolutionary for our grandmotherly medical journals." But, dense as is our own ignorance, we are told that there is one other journal which lags even behind us in knowledge of the truth about infinitesimals. Which journal that is we are not told, but says the editor, "our readers will have no difficulty in guessing." So that, after all, we are not as grandmotherly as we might be. Let us hope that as time goes on we may attain to the enviable position of this more mature progenitress. At present we can only envy its riper experience. The *British Homœopathic Review* thinks us very blind not to see the value of the minute doses of silica and other drugs in spa waters, but it is chiefly hurt that we should have treated lightly Dr. Proctor's "thoughtful remarks" about the combination of mystery and truth in homœopathy. Is there not mystery in all laws? "Can those who ridicule us because we cannot explain the law of similars, explain the action of the law of gravity? Why do bodies attract one another with a force inversely proportional to the square of their distances and directly proportional to their masses? Is there not mystery in this, and is not this a mystery that has led to everlasting discussion amongst astronomers? Is, then, this mystery a fit object for the laughter of our orthodox contemporary?"

Various Mysteries.

WE are not sure that we understand what is intended by "this mystery" in the last sentence, but if either the law of gravity or the laws of the attraction of bodies in space be meant, we hasten to assure our contemporary that from our school days upwards none of them ever suggested one merry thought. Life would have been more joyous if they had. We are not amused at mysteries *quâ* mysteries. For some, such as the mystery of holiness, we have the greatest respect; for others, such as the Druce mystery, we have but little. The greatest mystery about homœopathy is that since almost every one of Hahnemann's doctrines has by this time been denied by one or other of his followers, and some of them, we believe, officially abandoned by all, that the cult has any cohesive force remaining. But we have to thank our critic for one graceful concession. He quotes our remark that the "everlasting discussion that rages abut homœopathy . . . . . can lead to no useful result," and adds, "There is truth in this." We are obliged for the admission, and will endeavour to bear it in mind. Where real knowledge resides criticism will elucidate it; but where mystery is the bulk of the stock-in-trade discussion is about as useful in clearing it up as letting off pop-guns would be in dissipating a London fog. There always will be eccentric people who prefer the gloom of the fog to the sunshine of the mountain, and to them the arcana of homœopathy are likely to prove irrestibly attractive.

Human Sacrifice.

As an example of the bewildering state of the mind of the true homœopath, we cannot do better than refer to Dr. Burford's evidence before the Royal Commission on Vivisection, which is given in the same number of the *British Homœopathic Review*. It occupies some twenty-five pages, and the reader who can deduce from it much more than that Dr. Burford wishes drugs to be tried on man rather than on animals, is possessed of greater subtlety of intellect than ourselves. Dr. Burford, a homœopathic practitioner, came before the Commission as representative of the "World League of

Opponents of Vivisection," and after having answered nearly a hundred questions, said that he could not say whether the views he expressed were those of the League he came to represent or not! He believed, however, that they wished the subjects of experiments with drugs to be men and not animals. New surgical operations and new suture material, and so on, he thought, also, should be tried on man before being tried on animals. Besides these extraordinary doctrines Dr. Burford held that experiments on animals had greatly advanced physiological, pathological, and diagnostic knowledge and skill, and that though he would restrict experiments on animals with drugs to such as had been performed on man previously, he would not abolish the practice, and he was not sure whether he would abolish physiological demonstrations on animals to students. Moreover, he thought that serumtherapy had been of great use, and had been discovered by experiments on animals, and though he could not suggest how it could have been discovered otherwise, he believed there was no reason why it should not have been found out by homœopathic methods. How anyone holding such views can represent a League of Opponents to Vivisection, or how he can expect to get serum from animals except by experiments on animals are points that take the breath out of the plain man's body.

Worcester C.C. and Medical Inspection. The opposition which the medical inspection of school-children will meet with if not conducted in accordance with parents' wishes is forcibly illustrated by an occurrence at Bromsgrove. The Worcester County Council have appointed a medical woman to inspect schools under the Education Committee, and it is alleged that she visited certain schools, inspected the heads of the children, and found 70 per cent. of them to be infected with lice. Cards directing the parents' attention to the fact and suggesting treatment were sent home by the children in unsealed envelopes, it is said. The parents were exceedingly angry, many of them denied the diagnosis, and one parent went to his own doctor in the evening and obtained a certificate saying the child's head was clean. On the next occasion of the lady's visit a hostile demonstration was organised by the parents. The position was considered at a meeting of the Bromsgrove Education Committee, and the following resolution was sent to Worcester: "That this committee beg to call the attention of the Education Committee to the fact that considerable friction has been caused on the occasion of the inspection by the medical officer at the schools, and they view with alarm the manner in which the examination was conducted, and the careless way in which the warning cards were distributed."

Need for Tact. Now these proceedings seem to us to be precisely of the kind that may threaten the medical inspection of schools with the unpopularity that attached itself to compulsory vaccination. We are not in a position to judge of the correctness or incorrectness of the statements made, but it is quite clear that bad feeling has arisen, and unless the medical inspection of school-children attracts the gratitude and good-will of parents in bulk, this most useful provision will incur odium which may be fatal to it. It is not necessary to remind British readers that no method that smacks of autocracy or high-handedness or want of consideration will ever be acceptable to the working-classes; indeed, it would be a bad sign if it were. The question of dirty heads, as every medical man knows, is one which raises more indignation in a poor parent's breast than anything else, even when lice are demonstrably present. On the other hand, if a mistake be made, the indignation has good basis in fact. Only by the most tactful methods would it be possible to transform a school containing anything like 70 per cent. of lousy pupils into a thoroughly clean one; wholesale condemnation at one fell swoop would be likely to sap all the medical inspector's influence for good for ever.

LEADING ARTICLES.

THE RIGHTS OF HOSPITALS IN COMPENSATION AND OTHER CLAIMS.

THAT the services of honorary staffs are utilised in various ways by patients in enforcing claims for money from employers and from other sources is, of course, an established fact. We have often complained of the way in which public bodies like school boards obtain certificates gratis from the hospitals as to the fitness or otherwise of scholars for school attendance. We regard that as an unfair advantage taken of the hospital medical staff at the expense of their professional brethren outside. The hospitals have only to be firm and united in the matter and a considerable slice of legitimate income would be restored to the general practitioner, or, failing that, a small fee might be exacted by the hospital authorities for every such certificate granted by one of their staff. As to the average club certificate, there is little to be said in the case of poor patients, although in their case the document is asked for with the avowed object of entitling the holder to a more or less substantial money payment. Another kind of claim, however, has arisen of late, namely, those of domestic servants and workpeople under the Workmen's Compensation Act. At the present moment there is no knowing what may be the exact relation of any injury, trifling or severe, to a future claim. A mere trivial punctured wound, if sustained in the course of a labourer's occupation, may become septic and lead to prolonged sickness or death. In such a case the patient may be treated in the first place at a public hospital, and a certificate granted stating his disability to work for a few days on account of the accident. Should the after-course of affairs be of the untoward nature above indicated, then the hospital certificate, freely given in the first instance to help a working man tide over an apparently trifling emergency, would assume a vastly different importance as the chief documentary proof in establishing a claim for two or three hundreds of pounds sterling. More than that, a precisely similar train of reasoning applies to almost all cases of sickness amongst workpeople in active occupation. The basis of the law of workmen's compensation has been so greatly broadened that at any moment a great number of maladies may be asserted to have arisen directly or indirectly out of a particular occupation. Under these circumstances there seems to be good reason for all medical men engaged in honorary or resident hospital work to pay some attention to the question of certificates granted to patients of medical charities. Indeed, the subject might well be brought prominently before the professional bodies which deal with matters of practical politics. In point of fact, it is not altogether impossible to imagine that the medical charities may find on an enquiry that it would be desirable to refuse sick certificates in any shape or form. It is tolerably certain that such an action would to some extent relieve the unfair hospital competition of which general practitioners complain. As regards payments from patients to which the medical charities may be said to have a moral right, much attention has been drawn to the point by a recent action of Mr. Justice Darling. In a case before him in which damages were found against two motor omnibus companies for personal injuries caused to a lad, the Judge mentioned directed that, out of the sum awarded, a certain amount should be handed to the hospital where the injured boy was treated. In a letter to the *Times*, commenting upon that direction, Mr. Justice Ridley says:—"I quite concur with this, and think it right and proper; but I have often thought when trying cases of this kind, where injuries caused by the negligence of defendants have been treated free of expense to them in a hospital (instead of by a doctor for whose charges they would have had to pay), that it would not be unfair if the Court had power to add to the damages such a sum as they might, within certain limits, assess as a contribution to the hospital proper to be paid by those who did the wrong." Judge Ridley asks if it would not be possible for Parliament to find time for the passing of such a measure, short, beneficial, and non-political. Viewed in the light of past history, we fear no British Government is likely to favour such a proposal for generations to come. Even the present Government, which claims to be liberal and progressive in its social legislation, has recently saddled the medical profession with another gratuitous duty, to be discharged under pains and penalties, under the Notification of Births Act. On all hands it is evident that the economic relations of the hospitals, the public and the medical profession stand in urgent need of revision.

CURRENT TOPICS.

The Bristol Infirmary Dispute.

WHATEVER may be the upshot of the stand taken by the honorary medical staff of the Bristol Royal Infirmary against the attempt of the Board to interfere with their private affairs, it is encouraging to see the loyalty with which the local medical profession has rallied to their support. They have issued a temperate, clear and dignified address to the governors of the charity in question. They "view with dismay" the rule curtailing the holding of outside appointments and restricting the private practice of the honorary staff. If enforced, they say such a rule will inevitably lead to the resignation of the entire staff, and the disaster to this noble institution will be final and irremediable. They urge the governors to vote "against this most objectionable rule in its entirety." There are no fewer than 226 signatures to this document. It is a most gratifying sign of the times to see medical men coming forward collectively in defence of their reasonable rights and privileges. In the present instance their united action makes it practically impossible for the Board, supposing them to be stiffnecked and strong enough to carry their obnoxious rule, to replace the medical staff. It is inconceivable that any medical man would have the temerity to apply for one of the vacant posts in face of such a manifesto signed practically by the whole local profession.

Earth Fertilisation by Seed Inoculation.

A DISCOVERY of vast potentiality has been announced by Dr. Bottomley, Professor of Botany at King's College, London. It is nothing less than that of the fertilisation of soil by inoculating seed with a nitrogen-producing microbe. The possibility of turning barren land into fertile fields thereby afforded is certainly alluring, for it satisfies a scientific dream that has long haunted the mind of mankind. The present announcement bears all the air of authenticity and of well-ascertained results. It is stated, for instance, that a small holder near Gloucester "inoculated" a quarter of an acre of peas, from which he obtained 33½ pots of peas, selling at £7 18s. 9d., as against .14 pots, selling at £2 5s. 6d. from a similar area dressed in the ordinary way with 1 cwt. of superphosphates and sulphate of potash. It is further said that Mr. W. T. Stead, the well-known journalist, has acquired the exclusive right of handling the new material for twelve months from January next, the same being supplied to him at the rate of 5s. a gallon. Mr. Stead's avowed purpose is not to make a fortune out of the monopoly, but to confer an enormous boon upon the United Kingdom by bringing many millions of acres of barren land into cultivation. The Americans have a corresponding but greatly inferior article, the price of which is thirty shillings per gallon. Mr. Stead's price is six shillings, of which half will go to Dr. Bottomley and the other half to advertising and pushing the sale of the stuff. If there be any surplus to dispose of, he proposes to endow a professorship for biological and botanical research. It is to be hoped that there is a more practical and substantial foundation for this "discovery" than for that announced from the Continent a year or two ago, whereby agriculture was to be revolutionised all over the world. Dr. Bottomley's researches appear to have been founded on the original observations of Hellneght, in 1886, upon the relation of bacteria to the roots of leguminous plants.

A Sign of the Times.

IF there be any truth in the proverb that coming events cast their shadows before them, then there is something of significance in the proposal of the medical staff of the Montrose Royal Infirmary to charge fees to certain patients in that institution. This is indeed taking the bull by the horns, and although the suggestion was not adopted by the management, it nevertheless gave rise to considerable discussion. The staff appear to have confined their proposal to private patients sent by themselves to the hospital. As a general rule, the established ethical usage in the medical profession is scrupulously to avoid anything remotely suggesting a fee to hospital patients, and it is not a little startling to hear a plan for systematic payment coming from a medical quarter. The objections to such a course can hardly be otherwise than abstract and sentimental. If the whole matter be resolved into a logical analysis, one of the fundamental points will be the definition of a hospital, and whether a medical charity is founded for the benefit of those who can pay fees. If the hospitals attract and foster patients who can pay fees, are not medical men entitled to be paid for their services? On what grounds do the hospitals use funds collected for the poor for the purpose of relieving the well-to-do? These questions have long vexed the mind of the general practitioner, but Montrose has presented them for the first time in concrete form.

Sylvester's Method v. Schafer's.

SOME very interesting experiments on the comparative value of Dr. Sylvester's method for resuscitation of the apparently drowned, and that recently introduced by Professor Schäfer, were made at the London Hospital last week. Mr. W. M. Fletcher, of Trinity College, Cambridge, lectured at that institution on behalf of the Royal Life-Saving Society, and thereby attracted the attention of the staff and students to the new method. It was accordingly arranged that a trial should be made of the two plans, several students offering themselves as subjects for the experiment. The tests were carried out under the supervision of Dr. Keith and Dr. Leonard Hill in one of the small operating theatres. The experimentee had his face covered with an india-rubber mask to which was attached an india-rubber tube communicating with a spirometer. The experiments consisted of two minutes' successive trial of the two methods, the student endeavouring not to breathe voluntarily during the ordeal. No marked difference was obtained by the test, but it was admitted to be unsatisfactory because of the difficulty of excluding voluntary efforts. Consequently it was decided to anæsthetise a volunteer and make the experiment again. Although the conditions were, of course, very different from those obtaining in a person apparently drowned, the result showed a marked difference in favour of the older method. The respiratory exchange shown by Sylvester's plan mounted to between 500 to 600 cubic centimetres, whilst under Schäfer's it was not more than 300 to 400, and sometimes only 200. Although Schäfer's method is certainly more convenient in many ways, and less exhausting to the operator, it would seem that it is not so effective in filling the lungs with air and conducting the exchange.

Dakhyl v. Labouchere.

THE echoes of the Dakhyl *v.* Labouchere case have not been so loud and frequent as the extensive reports given to the proceedings by most of the newspapers seemed to presage. *Truth* is naturally pleased, but it treats its opponent in a very magnanimous manner, even expressing sympathy that he has been put to so much expense. We have already congratulated our contemporary, but we cannot help reverting to the commendable persistency with which Mr. Labouchere refused to take the first, and obviously ridiculous, verdict against him, and fought the case through to a finish. No one will lose faith in a quack of the rankest species if denounced merely in a medical paper, and Mr. Labouchere has silenced a number of the most blatant of them in the course of his journalistic career. Indeed, the very rules by which medicine seeks to control boastful pretenders in its own ranks are resented by the public. We are specially glad, then, to call attention to one sentence in *Truth's* article on the subject. It runs: "My observations on the Drouet Institute, as well as on Dr. Dakhyl, were prompted by regard for the interest of the public, not of the medical profession, *but in the main the two interests are identical.*" [The italics are our own.] That point we have maintained over and over again, but the public will never admit it. Such articles as appeared in other journals dealt very gingerly with the topic. It is a delicate one for most of them, as the main advertisement revenue of most is derived from fraudulent quack announcements. We fancy that many journals anticipated a repetition of the first verdict, and would have been glad to enlarge on the exclusiveness of the profession in having no truck with men of the Dakhyl type. As the verdict was against that individual they were content to evaporate into generalities about the exact definition of a quack, and similar banalities. It is a shocking thing to reflect that nearly the whole of the great development of journalistic enterprise of the last thirty years is built upon the most pernicious form of extorting money from the poor, namely, by gross lying to them about their health on which their livelihood depends.

A Round Robin.

That the Midwives Act is running a chequered career is being demonstrated almost every week. One of the most serious attacks on its administration was announced a few days ago by Mr. Coroner Baxter at a Poplar inquest. The investigation was concerned with a child who died a few hours after birth. The Coroner mentioned the fact that he had received a round robin from medical men, refusing to attend cases where there had been a midwife or "handy woman." It is impossible to avoid a feeling of sympathy with qualified medical men who decline to be made the instruments of deliverance from the Nemesis of unskilled or partially-skilled midwifery. The Legislature appears to have reckoned without their host in passing the Midwives Bill. The medical practitioner, against whom they were pitting an ignoble rival, was expected to take his part in the programme without demur. If he follows to any great extent the example of the Poplar practitioners, the Midwives Act will speedily become a dead letter, for the public will have to choose between medical men and midwives. There will be no half-way house if the medical profession make up their mind to unite against this insidious form of unqualified competition.

Sanitation in Irish Schools.

Some appalling information as to the condition of the buildings of the primary schools was given the other day in a public speech by Mr. Starkie, the Resident Commissioner of National Education and official head of the primary school system in Ireland. Everyone must agree in the view that it is of the utmost importance to the health of the nation that the schooling of the young should take place under proper sanitary conditions—that the school buildings should be clean, bright and airy, and that the children should learn something of hygiene, not merely from perfunctory primers, but from practical example. The Resident Commissioner, however—and he ought to know—is reported to have said: "They saw in the schools insufficient floor space, insufficient heating, insufficient class-rooms, and no means of cleanliness such as the simple form of lavatory. One of the inspectors, reporting as to a school in Ballymacarrett, Belfast, stated that on the day of inspection there were 401 pupils crowded on a floor space intended only for 209. There were 61 first standard pupils in a room 14 by 9½ feet, or 133 square feet in all. In another room there was 1¾ square feet for each unit. Thus the Belfast class-room was not as bad as the Black Hole of Calcutta by one quarter of a foot for each unit." We understand that attendance at school is compulsory in Belfast. It is hardly necessary to comment on these scandalous facts. The cruelty of compelling children to herd together in this fashion for some five hours a day is only equalled by its folly. Education is supposed to be given for the advantage of the child. In what possible way can a child be benefited by instruction given under such conditions at the expense of the health of its life-time? At no period of life are hygienic conditions more necessary than in childhood. It would be out of comparison better to let children grow up unable to read, write, or cipher than attempt to teach them under the conditions that obtain in Belfast.

The Dublin Hospitals and Tuberculosis.

A step of considerable importance has been taken by Her Excellency the Countess of Aberdeen in endeavouring to establish special dispensaries for consumption in Dublin. At present there is no special dispensary for consumption, and tuberculous patients attend the Poor-law dispensaries and dispensaries of the clinical hospitals along with other patients. Her Excellency as President of the Women's National Health Association, has written to the several hospitals of Dublin, asking each of them to consider the possibility of starting, on one day in the week, a special dispensary for tuberculous patients. By this means, there would be on each day of the week a special dispensary within reach of any part of the city. If this were done, and a record of the patients kept, the Women's National Health Association would, on its part, guarantee to send visitors to the patients' homes who would give instructions as to the means to be adopted to prevent the spread of the disease. The various hospital boards have the matter at present under discussion, and we are unable to say at what decision they will arrive. It is probable that in the first instance a conference representing the various hospitals will be held. The plan is in many ways a good one, and should add little to the expense of running the existing out-patient departments, though it is to be remembered that under present circumstances the chance of infection being spread by allowing tuberculous and other patients to attend the same dispensaries is slight. An alternative scheme, but one probably more expensive, would be to establish a central out-patient department, which might be worked in connection with the Royal National Hospital for Consumption.

Bob Sawyer Redivivus in Paris.

The medical student of to-day is a being far removed from the days of Albert Smith or Dickens. He is no longer the rollicking, rowdy trifler with snatches of work, but has become a serious, sober, hard-working lad, with brief intervals devoted to physical exercise. Now and then, it is true, there are scenes of disorder at some of our universities, chiefly in those north of the Tweed, at opening lectures and rectorial addresses. Collisions with the police, which used to take place occasionally at snowballing fights or torchlight processions, have not been heard much of lately. In Paris, however, the spirit of Bob Sawyer appears to linger. Two university professors appointed from the town of Nantes did not meet with their approval, and they proceeded to pelt them with tomatoes, eggs, and stale vegetables on their first appearance in the lecture-room. Outside, the mob of students were encountered by the police, who headed off the ringleaders, and thereby promptly quelled the disorder. The Paris University authorities have adopted the drastic step of closing the faculty until the end of the year. An exception is made in the case of students who, under ordinary circumstances, would have graduated before December 1st. The reason of this is that failure to pass within the prescribed date would entail an extra year of military service. The students demanded professors from the Paris schools, and resented those from the provinces.

PERSONAL.

H.I.H the Kaiserin visited the German Hospital at Dalston on November 14th, and conversed with some of the patients.

Her Royal Highness the Duchess of Albany opens the Infants' Hospital, Vincent Square, Westminster, to-day (Wednesday), at 3 p.m.

Dr. Ironside Bruce has been appointed Radiographer to Charing Cross Hospital, in place of Dr. Mackenzie Davidson (resigned).

Principal Donald MacAlister will preside at the session of the General Medical Council which opens on Tuesday next at 2 p.m.

Dr. Arthur E. Boycott, Fellow of Brasenose College, Oxford, has been awarded the Radcliffe Prize for 1907. Dr. A. G. Gibson received honourable mention.

Mr. Haffkine and Dr. Ashburton Thompson will read papers on "Plague" at the Epidemiological Section of the Royal Society of Medicine on December 2nd at 8.30 p.m.

Dr. A. H. Spurrier has been granted the Royal permission to wear the insignia of the Second-Class Order of the Brilliant Star of Zanzibar conferred on him by the Sultan of Zanzibar.

A former President of the Lower House of the Austrian Reichsrath, Count Vetter von der Lille, who is over 50 years of age, has recently graduated as M.D. at the University of Vienna.

Dr. James Little, Regius Professor of Physic in the University of Dublin, has been appointed by the Crown to be a member of the General Medical Council for a further period of five years.

Sir James Digges La Touche, K.C.S.I., and Sir Shirley F. Murphy will be the guests of the Irish Medical Schools' and Graduates' Association at their dinner on Wednesday, November 27th, at the Hotel Cecil, London, W.C.

Dr. J. R. Bradford has been appointed Examiner in Medicine at Oxford; Professor Howard Marsh, Examiner in Surgery; Dr. J. W. Eden, Examiner in Obstetrics; and Dr. T. M. Legge in Forensic Medicine and Public Health.

Dr. Koch, who has returned to Berlin after an absence of 18 months in German East Africa, has been promoted to the rank of Wirklicher Geheimer Rath, with the title of Excellency, in recognition of his valuable researches into the causes of the sleeping sickness.

Mr. Rickman J. Godlee, F.R.C.S., Surgeon-in-Ordinary to H.M. the King, Surgeon to University College Hospital, will deliver the Bradshaw Lecture at the Royal College of Surgeons, England, on December 5th, the subject being, "The Prognosis and Treatment of Tubercular Disease of the Genito-Urinary Organs."

The period of office of Mr. Clinton T. Dent, F.R.C.S., as a member of the Court of Examiners, Royal College of Surgeons of England, having expired, the Council announce the vacancy in our columns to-day. Mr. Dent, however, is eligible, and will, we understand, offer himself for re-election.

A Clinical Lecture

ON

A REFERENCE TO SOME TUBERCULAR DISEASES OF THE KNEE JOINT AND TO THE TREATMENT OF THE SYNOVIAL CAVITIES.

By R. L. SWAN, F.R.C.S.I.,

Surgeon to Dr. Steevens' Hospital and to the Orthopædic Hospital, Dublin.

Gentlemen,—You have seen in this hospital a number of cases of disease of the knee-joint, differing in their onset; in their appearance; and their clinical symptoms, to which the generic term "tubercular" was applied. Many of those, although springing from the same ætiological factor, were as varied, as regards the tissues involved and the appropriate treatment, as if in each case a different disease existed. In the limited time at my disposal I shall only touch on the outskirts of this subject, in an effort to illustrate some diagnostic features in tubercular disease of the knee, and, so far as is yet known, the most successful methods of dealing with some of its forms.

For practical purposes, we may broadly divide tubercular disease of this region into two varieties: (1) Of the bones; (2) of the synovial membrane, recognising the fact that as the focus, wherever originally placed, has a progressive tendency, both structures may become involved from disease of either.

There are three situations towards which the osseous focus may extend:—

1.—Outside the limits of the synovial membrane.

2.—At the point of reflection of that tissue.

3.—Towards the articular surface, and by absorption of the cartilage, directly infecting the joint.

1. The local signs will be marked. There will be pain and lameness, and an abscess will develop. The joint, however, although sometimes showing effusion, may altogether escape infection. In such cases close attention to surgical details, especially to drainage, and the use of bactericidal injections are of great value.

2. Here the synovial membrane becomes thickened at the point of infection. This condition spreads through its entire extent, and abscess at the point of primary infection is not infrequent.

3. The train of symptoms following direct infection of the joint through the eruption of a softened tubercular focus through the cartilage are acute. There is severe pain, and the entire joint is soon infected.

The frequency with which tubercular disease originates in the synovial membrane and in the bone is somewhat greater in the first (351 synovial and 281 osseous—König). In the 281 cases referred to the patella was affected in 33, the femur in 97, the tibia in 107, and several bones 48. Primary foci in the patella may soften and burst externally, but frequently cause infection of the joint. Granulation foci may be met with near the femoral condyles, and most frequently the internal, which is also the seat of extensive tubercular lesions in children. These do not infect the joints so frequently as in adults, but develop toward the surface. Large tubercular deposits are often met with in the head of the tibia, sometimes softened and large enough to merit the name of caseous abscess. Tubercular foci may remain latent in bone for a prolonged period, and may undergo change into a calcified and desiccated tissue. During the period of primary deposition the symptoms are vague. There is little or no pain; there is a feeling of fatigue, and sometimes an effusion into the joint, which subsides when rest is enforced.

If the fortunate result of calcification of the focus occurs, there are no further symptoms.

I shall not here allude at all to the treatment of knee joint disease associated with osseous lesions. I have nothing new to mention, and you have constant opportunities of seeing the application of erasion, excision, or general surgical principles to those cases.

Hydrops Tuberculosis.—Chronic synovitis, scrofulous synovitis, recurrent synovitis of the older authors is frequently met with. It is most common in early youth and young adults, but may be seen in persons of middle age. Its origin may be ascribed to some trivial injury. The joint may be enormously distended, and the synovial membrane has been known to rupture spontaneously (Nélaton): "Under the influence of rest and treatment, the swelling usually subsides, to reappear when walking is resumed."

Degenerative changes in the diseased synovial membrane usually occur as time goes on. A gradually increasing thickness is perceived, some pain after walking is felt, and occasionally a tendency in certain movements to locking of the joint. In such cases it will be found that masses of fibrin have been detached from the synovial membrane, and have become moulded by the movements of the joint into pyriform masses (melon seed bodies), floating in a grey or semi-opaque fluid mixed with shreds and flocculi of fibrin, a crepitating sensation being imparted to the fingers on examining the joint from the contact of those masses.

In some cases the synovial membrane is seen to be studded with polypoidal sessile masses, red on the surface, and secreting a sanious fluid; sometimes on removal of the fluid by rest it is possible to discern those masses, especially in the suprapatellar pouch.

Tubercular empyema of the knee is sub-acute in its nature, and is met with in persons of low vitality showing other signs of tuberculosis. An acute form of empyema is met with in young children, accompanied by pain and pyrexia. The synovial membrane is said to show miliary tuberculosis.

Synovial Fungus (White Swelling).—Those cases are happily not now so often seen, or only in cases (usually the children of the very poor) who have been neglected. An advanced condition of disease exists. It may either follow primary hydrops, or commence with initial signs of synovial thickening. There is generally pain referred to the tibia or the centre of the joint. The pain may be intermittent, and is mostly felt at night. The synovial membrane progressively thickens. The knee attains a large size. The skin is shining, with blue veins ramifying on it. Later on the cartilages become involved, and suppuration occurs.

It is in disease of the synovial membrane that we may hope to restore functional usefulness to the joint in many cases.

Several methods have been adopted.

1st.—Most surgeons recommend that the flexed position usually existing should at first be rectified by extension, followed by prolonged fixation for 12 or 18 months.

2nd.—Venous congestion by Bier's method.

3rd.—Injections of iodoform glycerine into the joint. It may be remarked that the first method does not aim at functional restoration of the joint, and owing to the time involved is not applicable to the poor.

With regard to Bier's method and iodoform glycerine injections, the results are not satisfying. Evidence in the subject shows in some cases improvements, in others none.

In the year 1904 I read a paper at the Surgical Section of the Royal Academy of Medicine, showing the results of the application of pure carbolic acid to the interior of the joint in tubercular synovial disease, and describing the method of operating. Since that time I have treated numerous cases with very satisfactory results. It is applicable not only to recurrent hydrops, without synovial thickening, but also to the fibrinous form of tubercular disease, to the vascular and polypoidal disease of the synovial membrane, and to synovial empyema.

The only modification in the method of operating is the position of the incision, originally as described in my paper of 1904. I made a transverse section of the patella. Later on I adopted an incision of the inner side of the joint, but I have recently adopted the curved incision of trachea, at the outside of the joint, and have in some cases removed a piece of the tibia attached to the ligamentum patella, in order that full access to every part of the joint should be attained.

The restoration of function is usually complete, and, so far as I have seen, there has been no relapse. Only a few days ago I received a letter from a soldier in the Bedfordshire Regiment stationed at Jhansi, on whom I operated four years ago in this hospital. He says: "My knee never gives me any trouble, and I can march as well as anyone else." The following are a few illustrative cases:—

R. F., a shopkeeper from the West of Ireland, has been troubled with his knee for two years. There is considerable effusion, with some synovial thickening. In September, 1905, I opened the joint and gave exit to a whey-coloured fluid, with some shreds and fibrinous masses. The synovial membrane was roughened, and of an ashy grey colour. I washed out the joint, removing all the fibrinous shreds with a sterilised loofah, especially dealing with the sub-crureus bursa. Having dried the surface, from which a small quantity of blood was now oozing in some places, I applied pure carbolic acid freely with a stick, and again irrigated the joint, closing it without drainage. This man recovered perfectly—I saw him about a month ago. There was no trace of disease. Mr. E. was sent to me from Kilkenny by my friend Dr. O'Hanlon of Castlecomer. He had the usual symptoms of recurrent hydrops, and was in some anxiety about the possibility of retaining his situation owing to the frequency of his disablement. His knee had been affected for three years. When I saw him it was much swollen and somewhat flexed. Rest in bed was followed by subsidence of the swelling, which returned when walking was resumed. I advised operation, and with the assistance of Sir C. Ball, adopted the plan described above. Six months later he came in to show his knee, which, except for the scar of the operation, was indistinguishable from the other.

Mrs. R. C., a lady, æt. 32, from the South of Ireland, accustomed to an active life, has been two years suffering from her knee. I saw her in June, 1905, she was then unable to walk for any time without pain, and an increase of swelling in the joint, which was never quite free from effusion. An irregularly felt thickening of the synovial membrane was observed, especially in the suprapatellar bursa. She suffered some pain at night. I opened the joint on July 3rd. I found the interior of the synovial membrane of a purple colour and studded with sessile masses resembling purple grapes. The joint was filled with a red and oily looking fluid of the consistence of thin gum arabic. The synovial membrane was thickened and although apparently vascular, was not really so. The surface was subjected to a vigorous rubbing with sterilized loofah, irrigated and carbolic acid freely applied. In April, 1906, I received a letter from her husband stating:—"My wife is better than she has been for years. She can walk and ride as well as ever she did, and has no trouble with her knee."

J. S., a young man, æt. 23, in broken health, with scars of tubercular glands in the neck, was admitted into the Orthopædic Hospital (October, 1902). The knee showed a uniform swelling, was flexed and somewhat painful. On passing an exploring needle into the joint, a fluid resembling pus was withdrawn. The joint was incised, a large quantity of this fluid was withdrawn, the cavities thoroughly washed and rubbed, carbolic acid was applied, and it was closed without drainage. He made an uninterrupted recovery, and under the influence of good food and treatment, his general health became improved. I saw him some time ago; his knee showed no trace of disease.

The following condition may be mistaken for tubercular disease of the knee:—

1st. Syphilitic gummata.

2nd. Arthritis deformans.

3rd. Staphylococcus lesions from Brodie's abcess, either in tibia or femoral condyles.

4th. Charcot's disease.

5th. Gonorrhœal anthritis.

6th. A sarcoma, growing most frequently from the lower end of the femur.

7th. The non-tubercular form of loose cartilage.

8th. The bleeder's knee, met with in hemophiles.

Note.—***A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by James Morrison, M.D Lond., Hon. Physician Accoucheur Farringdon Dispensary and Lying-in Institution. Subject: Lingering Labour; its Causes and Treatment."***

ORIGINAL PAPERS.

THE ANATOMY OF THE SO-CALLED

LIGAMENTUM PECTINATUM IRIDIS

AND ITS BEARING ON THE

PHYSIOLOGY AND PATHOLOGY OF THE EYE. (a)

By THOMSON HENDERSON, M.D. Ed., Ch.B.
Nottingham.

The author stated that the so-called pectinate ligament was a part of and belonged to the sclera. The principle on which it was constructed was perfectly simple, being exactly the same as that which obtained in the fibres of the neighbouring tissue in which it lay, as an open network, composed of non-sclerosed interlacing fibres, which were in direct continuation with the circular and longitudinal bundles of the sclera surrounding the venous sinus of Schlemm's canal. The circular fibres were made out in tangential and transverse sections of the pectinate ligament, while the longitudinal fibres were seen in radial sections. The criterion of a true radial section was that it showed the anatomical connection and continuation often suggested, but hitherto never yet demonstrated, of

---

(a) Abstract of Paper read before the Ophthalmological Society, November 14th, 1907.

the hyaline layer of the ciliary body with the posterior limiting layer of the iris. Arising as a continuation of the innermost lamellæ of the cornea, the pectinate ligament should be divided into (1) a small outer or scleral portion, where fibres at the posterior end of Schlemm's canal became lost in those of the sclera, and (2) an inner larger or ciliary division, which could be still further sub-divided into (a) a portion which pierced the scleral ring to give attachment to the meridional fibres of the ciliary muscle, (b) a part which passed internally to the scleral ring to terminate in the connective tissue stroma of the circular portion of the ciliary muscle. None of the fibres of the ligament turned round into the root of the iris, as was described, but this appearance was the result of an oblique section and emphasised again the importance of studying only true radial preparations.

The iris root was attached to the circular bundles of the ligament at a point just posterior to the scleral ring, which attachment to the ligament was quite a different matter to fibres of the ligament being said to bend round into the iris, which they did not. He considered that the term ligamentum pectinatum iridis was thus not only altogether inappropriate but also wrong and misleading, as in man it was neither a comb-like structure nor was it a ligament to the iris. On this account, and because of its retiform or cribriform structure, and further, on account of it being a ligament in the true sense of the word to the two portions of the ciliary muscle, the term "cribriform ligament of the ciliary muscle" was much more appropriate. This ligament showed a most marked histological difference in its structure and nature at different periods of life. In youth it was cellular, while as age progressed it became more and more fibrosed. It was this physiological sclerosis in excess that he considered was the fundamental *causa causans* of primary glaucoma, in the causation of which two factors must be separated—the one constant, the other accessory.

The first and constant factor was sclerosis of the filtration network and a consequent diminished outlet.

The second and variable agent was vaso-motor in nature, and it was this which determined the acute attack, in which there was super-added to the first an inflow out of proportion to the available and already reduced channels of exit from the eyeball. Viewed in this light, all the phenomena of glaucoma, clinical and pathological, could be explained.

A closer study of this sclerosis of this filtration network gave a clear view of the process of development, and stages of formation of connective tissue, with definite histological proof that white and elastic tissue was not a direct conversion of the cell protoplasm, but was derived indirectly from alteration and transformation of a homogeneous substance which was itself the product of cellular activity. The alveoli of the filtration network were connected with the lymph spaces of the cornea and sclera, whose fixed corpuscles were brought into direct association with the endothelial cells of the anterior chamber. It was in consequence of this anatomical continuity that the cornea, by diffusion, received its nourishment from the aqueous. This fact would explain a great deal, and would have the utmost bearing on the pathology of corneal diseases.

A meeting was held in Chester Town Hall on November 12th for the purpose of promoting a memorial to the late Dr. Everett Dutton, of Chester, in connection with the Tropical School of the University of Liverpool. Dr. Dutton, it will be remembered, died in the interior of Africa some time ago while investigating the cause of sleeping sickness.

PUBIOTOMY. (a)

WITH NOTES OF AN ILLUSTRATIVE CASE.

By THOMAS WILSON, M.D.Lond., F.R.C.S.Eng.,
Obstetric Officer to the General Hospital, Birmingham, and to the In-Patients at the Maternity Hospital.

In the intermediate degrees of pelvic contraction, when the conjugate diameter measures between 2¾ and 3½ inches, efforts have continually been made, at least since the middle of the eighteenth century, to devise a method of securing a living child without at the same time increasing the risks of the mother. These efforts have taken two directions—to enlarge the bony circle of the pelvis on the one hand, and, on the other, to procure a smaller child. When the patient is seen early in pregnancy, the latter object is sought to be attained by the induction of premature labour, which was first introduced as an obstetrical procedure in this country, where it was performed successfully by Macauley in 1756, and has ever since been regarded with peculiar favour.

The results of induction of labour in cases of contracted pelvis have been gratifying so far as the mother is concerned. Sarwey (Winckel's *Handbuch der Geburtshülfe*, Bd. 3, Tl. 1), in a collection of 2,200 cases in the 15 years from 1890 to 1904, found a maternal mortality of 32, equal to 1.4 per cent., 13 of the women having died of puerperal infection. As regards the child, the results are, as might be expected, much less satisfactory. In the same series of cases Sarwey found that 21.8 per cent. of the children were born dead, and another 15.5 per cent. died before the mothers were discharged from hospital, so that only 1,380 children, equal to 62.7 per cent. of the whole, were discharged living. The risks of the first year of life are greater in premature infants than in those born at full term, and on this point Sarwey inquired into the fate of 500 children in his collection who were discharged living from 12 different institutions. Of these, 406, equal to 81.2 per cent., were alive at the end of the first year. I have quoted these figures because they are the most favourable large statistics of the results of induction of premature labour that I have been able to find. It follows from them that not more than 50 per cent. of the children obtained by this operation are alive at the end of the first year, a result that calls for grave consideration, more especially at a time when the birth-rate in these islands shows a continuous and somewhat rapid diminution.

In cases where premature labour is indicated, and where craniotomy has often to be performed, a safe and not too difficult method of widening the bony pelvis has long been sought. For this purpose, division of the pubic symphysis was first recommended in France in 1768 by Sigault, who put the operation to a practical test in 1777. His patient had a rickety pelvis with a true conjugate diameter of 6.5 cm., and had previously borne four dead children. Two months after the operation the patient walked with considerable difficulty, and had a urinary fistula, which never healed. In the following two years 8 cases were made known, with the deaths of 4 of the mothers and 7 of the children. After such experiences symphysiotomy fell into disrepute until the latter part of last century, when it began to be recommended again by Morisani in Naples in 1866 and Pinard in Paris in 1892.

In the five years 1887 to 1892, Morisani operated on 55 cases, with 2 deaths of mothers, equal to 3.6 per cent., and 4 deaths of children, equal to 7.3 per cent. Pinard, in 1892 to 1894, performed 49 symphysiotomies, with 2 deaths of mothers and 5 of infants. Zweifel until 1899 had done the operation 35 times without a maternal death; then in 11 weeks he lost 3 mothers. His total maternal mortality was thus 6.5 per cent., while 4 of the children, equal to 8.7 per cent., died.

In this country symphysiotomy has never been regarded with general favour, and the only paper on the subject of any practical importance is one by Herman in the *Obstetrical Transactions* for 1901, Vol. XLII., p. 282, in which the author describes the subcutaneous method of performing the operation. A sharp tenotomy knife, having a blade an inch long, and one-eighth of an inch in diameter, is inserted opposite the middle of the symphysis pubis, and the joint is divided by cutting first down, then up. The advantages claimed for this method are simplicity, quickness, small risk of sepsis, insignificant hæmorrhage, absence of a gaping wound, and of subsequent scar. The only risk at present inseparable from the operation is considered to be that of injury to the urethra, which is likely to happen in excessive separation of the pubic bones in cases in which an attempt is made to deliver by symphysiotomy too large a child. In Herman's paper three cases are described, and four others referred to, as having been performed with good results in the London Hospital.

(a) Read before the Gynæcological and Obstetric Section of the Royal Medical Society, Thursday, November 14th, 1907.

The apparent simplicity of the operation is attractive, but on attentive consideration it appears that in the immediate neighbourhood of the part chosen for division are many structures which it is very desirable to avoid. The clitoris and its corpora cavernosa can hardly escape injury, and may be the sources of severe hæmorrhage difficult to control. Behind the symphysis is a large and important plexus of veins, while the bladder and urethra are in imminent danger of being crushed during the delivery of the child, or torn by the separation of the bones. In practice the operation has by no means proved to be an easy one, and its difficulties and dangers have resulted in its being rarely practised in this country.

In the last few years an attempt has been made, more particularly in Italy and Germany, to establish another operation for widening the bony pelvis by dividing the pubic bone instead of the symphysis. This procedure appears first to have been recommended by Champion de Bar le Duc and Stoltz at the beginning of the nineteenth century. According to Zweifel (*Zentralblatt für Gynäk.*, 1906, p. 1), Galbiati operated in 1832 by sawing through the pubic bone on one side, and in 1841 by sawing through the pubes on both sides, but the results do not appear to have justified an extensive use of the operation. In 1893 Gigli recommended that the pubes should be divided by means of his saw, which resembles a length of piano wire, but the operation was not actually employed on the living subject until five years later, when, in 1898, Bonardi employed it for the delivery of a IV.-para with a simple flat pelvis who had already had several difficult labours. Bonardi was soon followed by Calderini of Bologna, and Van de Velde in Haarlem, and then the operation rapidly became popular in Germany, where it has been specially practised by Döderlein, Leopold, Fritsch, Baumm, and Olshausen. In the last four years considerably more than 200 cases have been reported, and almost an equal number of papers and references have appeared, especially in the *Zentralblatt für Gynäkologie* (*a*).

Two methods of performing the operation have been devised—the open and the subcutaneous. In the former a free incision is made down to the pubic bone, which is then divided by the wire saw. This method has many disadvantages, among which the dangers of excessive hæmorrhage and of wound infection are the chief. These dangers are avoided by the subcutaneous method, which is named after Döderlein, and is now almost universally preferred. In this method the patient is placed upon the back with the knees bent, and the thighs abducted and slightly flexed. A small vertical incision three quarters of an inch in length is made straight down upon the pubic spine; a large, specially constructed curved needle is then carried down behind the pubes, care being taken to keep the point of the needle in close contact with the surface of the bone. The point is made to emerge at the outer side of the labium majus, the wire saw is attached, and the needle withdrawn. The bone is then divided in a line nearly parallel to, and at a distance of half an inch from, the symphysis. As the bone is divided there is some bleeding, usually moderate in amount, but occasionally profuse; in the latter case pressure for a short time suffices to stop the loss. The child is then delivered by the method that appears best, the position of the legs being varied according to circumstances. Afterwards the upper wound is closed by one or two sutures, and the lower wound is also closed, or in some cases drained by a narrow strip of iodoform gauze. The pelvis is supported by a sandbag on either side, or by a broad strip of strapping across the front, or by an elastic bandage. The patient in most cases can get up without pain or discomfort on the sixteenth or eighteenth day.

This short description of the operation requires to be amplified in several important practical directions. The side chosen for the incision in vertex presentations is usually that on which the occiput lies, unless there is some contra-indication, such as varicose veins or hernia on that side. If the bladder is clearly on one side, the incision should be made on the other. Van Cauwenberghe claims that his observations on the cadaver show that widening is greater on the divided side, and in unequally contracted pelvis he recommends, therefore, that the cut should be made on the smaller side. The method of passing the needle varies with different operators. Usually this is done from above down, but Walcher and other operators pass the needle from below up, a method recommended by Tandler as the result of his anatomical researches The main source of bleeding in pubiotomy is injury to the crus of the corpus cavernosum on the side of the division, and by cutting down on the lower border of the pubic ramus, separating the periosteum, and with it the crus from the bone, and then passing the needle from below up, it is thought that injury to the crus may be avoided. Even then, however, there is a risk of the crus being injured by the movements of the saw in dividing the bone, and as the bleeding is usually moderate and easily controlled by pressure, the little additional complication appears to be unnecessary.

In the method of delivery the greatest variation has appeared. That which has been chiefly employed is extraction by forceps, though many operators have preferred version. Recently there has been an increasing tendency, after dividing the bone, to leave the labour to the natural efforts. This was first recommended by Zweifel, and tried by Döderlein, and it is claimed that it offers less danger to the maternal soft parts, and at the same time gives a better chance to the child. On the other hand, it has been suggested that it increases the liability to the formation of a hæmatoma. The position of the patient's legs at the different stages of the operation requires careful attention, and will be considered in connection with the description of the changes produced in the pelvic cavity by the operation.

The dangers of the operation include, in the first place, bleeding, which has rarely been so copious as to call for opening up of the wound and the application of ligatures; generally the hæmorrhage is moderate in amount, and easily controlled by pressure. A slight degree of hæmaturia has been observed in a considerable proportion of cases, and appears usually to be caused by bruising of the wall of the bladder against the cut edges of the bone. In one case reported by Baumm the bladder was ruptured; in no case have I seen mention of injury to the urethra. Commonly in the hours after delivery a hæmatoma forms at the site of operation, but usually this remains small, and becomes absorbed without giving rise to trouble in the course of a week or ten days. Œdema of the vulva is commonly present in the first two or three days.

Œdema of the leg from thrombosis of veins has been several times described, sometimes on the same side as the division, and sometimes on the opposite. The risk of infection in cases that are placed under satisfactory conditions from the commencement of labour appears to be slight, and where the operation has been performed in cases of pre-existing infection the results have been on the whole satisfactory, as shown in cases reported by Schauta, Sitzenfrey, Arndt,

---

(*a*) In this country Berry Hart (Edin. Obst. Trans., 1903-04, vol. xxix.) was the first to try the operation, which has received the various names of pubotomy or pubiotomy, lateral section of the pelvis (Gigli), hebotomy (Van de Velde), and pubosteotomy. In Hart's case the operation was quite successful in effecting delivery, but the patient died of late chloroform poisoning. The case on which this communication is founded was the second to be performed here. In the May number of the "Journal of Obstetrics for the British Empire" for this year papers appear by Gibson and Hastings Tweedy, each of whom has performed the operation with success three times. In Tweedy's first case there were great difficulties and alarming complications, but the conjugate diameter measured only slightly more than 2½in. The total number of pubiotomies so far done in these Islands appears to be eight, all the children being born alive, and one mother dying from the results of anæsthesia.

and others. It has been suggested by Von Franqué that the operation can be done by hands which do not touch the genitals, and so can be carried out with reasonable safety in patients already infected. The principal danger arising out of the operation is that of laceration of the vagina, by which the subcutaneous division of the bone is converted into a dangerous compound fracture. This accident appears to be fairly common, especially in patients with narrow vagina and small vulva, and in such cases it appears better to make a deep perineo-vaginal incision on the side diagonally opposite to the division of the pubic bone. In every case the vagina should be carefully examined after delivery is completed, and if there is any laceration this should be treated by careful suturing, with provision for drainage. By these means it is possible either to prevent laceration taking place or to secure favourable union.

The results of the operation as regards both mother and infant have been excellent. The patient is able to get up on the fourteenth to the sixteenth day, and in a large proportion of cases to be sent home on the twentieth day. There is no difficulty or pain in walking. Union of the bones takes place first by formation of fibrous tissue, and later by bone. A considerable amount of callus is thrown out on the anterior surface of the bone, but it appears to be the rule, and certainly occurred in my case, that only an extremely small quantity is thrown out on the inner surface of the bone, an important observation from the point of view of subsequent labours. In cases where pregnancy supervenes soon after the operation, it has appeared in several cases that bony union is delayed for many months, and it has been claimed, though without sufficient evidence, by some observers, that a permanent widening of the bony pelvis takes place.

The following are the notes of my case:—

R. J., æt. 30, was admitted to the Birmingham General Hospital on October 23rd, 1905, for the eighth labour, which was estimated to be due on the 29th. The first four labours were terminated by forceps, all the children being born alive, the first and third still surviving. The fourth labour was attended by Mr. N. H. Turner, who recommended that the next should be induced at the eighth month.

I had first seen the patient in her fifth labour at term on September 28th, 1901. The labour was obstructed. On my arrival the vulva and anterior lip of the cervix were œdematous, the child was presenting in the left occipito-anterior position, the head more in the right side of the pelvis. By forceps an average sized male child was delivered, with an extremely moulded head, a deep groove on the left parietal bone parallel to the coronal suture, and facial paralysis due to pressure of the end of one blade of the forceps. The facial paralysis disappeared in a fortnight, and the child lived for 3¾ years. The pelvis was reniform, the sacral promontory forming a considerable projection into the brim. The external pelvic measurements were:—

Dist. sp. il., 25. cm.
Dist. cr. il., 27.5 cm.
Ext. conj., 18.75 cm.
Diag. conj., 11.5 cm.

The patient said she had been delicate as a child, was late in learning to walk, and had to work hard from her early girlhood.

The sixth labour was induced three weeks before term by hot injections and bougie on December 17th, 1902. Fifty hours after the introduction of the bougie a well-developed male child was delivered under chloroform by bi-polar version, with forceps to the after-coming head. The child was with difficulty revived, and died the same evening. The seventh labour was induced at seven and three-quarter months on September 3rd, 1904. Forty-five hours after the introduction of a bougie a female child 4¼ lbs. in weight and 17½ ins. long was easily delivered by forceps. It died the next day.

On the present admission the patient was said to have last menstruated on January 25th. Labour pains began on the evening of November 21st, 1905, and at 3 p.m. on the 22nd the cervix was fully dilatable. The child lay with its back to the right, the head freely movable above the brim; the fœtal heart, 150 to the minute, was heard far back on the right side. About three pints of liquor amnii escaped when the membranes were ruptured. In spite of strong pains, the head, which entered into the third vertex presentation, failed to engage firmly.

Operation.—The patient was anæsthetised, and forceps applied. Forcible traction was then made at intervals of three minutes, but entirely failed to bring the head through the brim. Pubiotomy was determined upon, and was carried out by the modified subcutaneous method. A vertical incision 1¼ inches in length was made upwards from the pubic spine on the left side. The incision was carried down to the bone, and a Gigli's saw was then, by means of a Seeligmann's director, passed downwards close to the posterior surface of the left pubic bone, and brought out at a point on the outer side of the left labium majus. The bone was easily sawn through, and the divided ends immediately sprang apart, leaving a gap of ¾ inch or thereabouts. The upper end of the division was a little internal to the pubic spine. The forceps were again applied, and the child very easily delivered, the occiput coming forward into the second vertex presentation at the outlet. Ergot was now administered subcutaneously; the placenta was expressed from the vagina after 15 minutes. The upper incision was closed by silkworm gut sutures; the lower small one had ragged edges from the action of the saw; it was partly closed by one suture and drained by a small strip of iodoform gauze. A broad strip of adhesive plaster was brought across the front of the pelvis from side to side. The child weighed 8 lbs., and soon began to cry vigorously.

Result.—The subsequent course of the puerperium was normal in every respect. There was moderate œdema of the left labium majus, which gradually disappeared in seven days. The upper wound united by first intention, and the lower one was firmly healed by the end of the second week. On the twelfth day after operation a thick callus was felt along the line of division on the outer aspect of the bone; on the inside the division felt like a slight depression, and there was no exudation making prominence above the surface.

At the end of the third week the patient was allowed to sit up, which she did quite comfortably. Two days later she was radiographed, a clear space about ¼ inch wide showing between the divided portions of bone. During my absence from hospital for a few days, my Resident interpreted this clear line to mean that no union had taken place; he therefore ordered the patient back to bed. As a consequence, when I next saw the woman she had developed a well-marked neuromimetic paralysis of the left leg. Every movement of the limb, including abduction, adduction, and rotation of the thigh, could be performed perfectly by the woman as she lay in bed; but when asked to stand she collapsed, and would have fallen to the right, the left leg at the same time becoming extended and rigid. There was no affection of sensation, the limb remained normal in nutrition and appearance, and there were no alterations in the deep or superficial reflexes. Electricity, massage, and the exercise of patience were followed in a few weeks by the return of normal power in the limb. The patient has had no further pregnancy, but has remained well and able comfortably to carry on all her household work. The child died at the age of 1½ years from some wasting disease.

The operation, in my opinion, is a good one, appearing to possess the advantages claimed for symphysiotomy, while avoiding some of its more serious disadvantages. The wounds are small, and placed well away from the vaginal orifice; the divided bone readily unites, first by fibrous and later by osseous tissue. The situation of the division on one side of the middle line greatly lessens the risk of injury to important structures. The only likely source of hæmorrhage is the crus of the corpus cavernosum, which is usually divided at the same time as the bone is sawn through; pressure for a short time suffices to stop the bleeding. The relations of the wound in the bone to the clitoris, the bladder, and more particularly to the urethra, are much less close than in symphysiotomy, and thus the particular dangers of the latter operation are obviated.

With the same degree of separation of the bones, the amount of widening of the pelvis, according to comparative observations made on the cadaver by Sellheim, is the same after pubiotomy as after symphysiotomy, but after the former operation the separation requires three times greater force than after symphysiotomy. The divided ends of the bone are held in contact by the attachments of the adductor muscles, and only separate to an extent sufficient to allow the passage of the child. The sudden springing apart, which has occasionally been attended by serious injuries to the soft parts in symphysiotomy, is not likely to occur here. The limit of safe separation of the divided bones appears to be about 6 cm., any further widening being likely to cause rupture of the sacro-iliac joints. Morisani said that after symphysiotomy with a separation of 6 cm., the conjugate diameter is increased by 13 to 15 mm., and that the bulging of the soft parts increases the enlargement to about 22 mm. Döderlein says that in this amount of separation the superficial area of the brim is increased by about half, from 105 to 155 square cm.

As the bones become separated the inclination of the pelvis is increased (Ahlfeld), while the cavity becomes funnel-shaped and at the same time shallower from above down, the last effect depending upon the raising and flattening of the pelvic floor by the unyielding sacro-sciatic ligaments. Kroemer draws special attention to the effect upon the separation of the bones produced by alteration in the position of the legs.

The indications for the employment of pubiotomy are the same as those for symphysiotomy. The pelvis must not be anchylosed, and must have a conjugate diameter of not less than 2¾ inches in a flat and not less than 3 inches in a generally contracted pelvis; below these limits Cæsarean section is a safer and better operation. If there is a probability that the patient is already infected, craniotomy will usually be preferable. Auscultation must afford proof that the child is living and strong. Labour must have advanced so far that the cervix is fully dilated or fully dilatable, or dilatation should have been completed by the hydrostatic bag; sufficient time must be allowed for the natural efforts to mould the head. If, then, in spite of strong pains, no progress is made in two hours in a multipara, or four hours in a first labour, or if the maternal pulse rises so that it remains at 100 in the intervals between the pains, delivery should be attempted by the high forceps operation under chloroform. The attempt should not be prolonged or repeated, but immediate recourse had to pubiotomy.

DEATH FROM HÆMORRHAGE FROM A MEDICO-LEGAL POINT OF VIEW.

Part III.

By PROFESSOR HENDRICK, M.D.,

Of Hamburg.

(Specially reported by our German Correspondent.)

Concluded from page 521.

Fatal hæmorrhage in the new-born occurs first from not ligaturing the umbilical cord.

Although omission to tie the cord occurs more frequently in precipitate labour, in concealment of birth, infanticide, and exposure, yet in these cases death from the omission is only rare, as under normal circumstances, after separation of the placenta, the umbilical arteries contract, the intima doubles on itself, thrombi form, and the blood pressure falls in consequence of the development of the lesser circulation. For this reason fatal hæmorrhage from the unligatured umbilical cord was formerly denied. On the other hand, others considered that death always followed when the tying was omitted. For an explanation of these contradictory views we must assume that for the occurrence of this fatal hæmorrhage special abnormal pathological and physiological conditions are necessary, although, from the small number of cases that occur, no sufficient proof of this has been established. These causes may be (Beckert) (54) an abnormal condition of the vessels of the cord, unusual thinness and softness, abnormal course, increased blood pressure when the lesser circulation does not become established or only imperfectly so, or hæmophilia.

Besides this, the following are to be considered as favouring factors (Caspar-Liman): When the cord is cut very close, although fatal hæmorrhage may occur when it is cut long (as case 448 of Caspar-Liman shows); further, when the division is effected by tearing and not by cutting; also when the cord is gelatinous and soft, as in such a case the ligature may become loose and fall off from the cord drying in. The diagnosis of fatal hæmorrhage from the umbilical cord is based on the general anæmic condition of the organs, anæmia from wasting being excluded; secondly, signs of bleeding having taken place, which may, however, have disappeared; thirdly, division of the cord between the umbilicus and the placenta, and, fourthly, exclusion of all other causes of death. From the fact that the cord has been tied or left untied, no proof can be drawn either for or against fatal hæmorrhage, as a ligature can be applied after death, and, on the other hand, one applied during life may have become loose and fallen off, or it may have been tied firmly and bleeding still have taken place. Caspar-Liman mention three cases (Nos. 449, 450, 451) in which fatal hæmorrhage took place in spite of a long cord and firm tying. Finally, the diagnosis will be much strengthened by proof of the pathological or physiological abnormalities already mentioned.

In a case mentioned by Ahlfeld (56), the cord, which was very thin and poor, was torn by the midwife 3 cm. from the umbilicus, and the child died from fatal hæmorrhage. On the right arm of the child was a furrow as from a ligature, which showed that a good deal of pulling had taken place. This rare case shows at the same time that caution should be used in condemning a midwife. Beckert (54) (Zeitschr. f. Med. Beamte, 1889, S. 569) quotes two cases by Haberda and Brouardel in which intra-meningeal hæmorrhage prevented the establishment of the pulmonary circulation, and rendered possible fatal hæmorrhage from the cord. Hæmophilia cannot be recognised on the cadaver, but only through heredity being proved.

The experiments of Caspar-Liman and Hofmann on the tearing-point of the cord, made by hanging on heavy weights of 500 to 1,000 grm., are of no practical value, as they are too little imitated on the living subject. We should not therefore conclude, when the cord is torn in a case of precipitate labour, that no blame attaches to the mother. It seems remarkable that no experiments have been made on the dead body to solve the question whether when the cord is firmly tied as the midwife is instructed to do it it can so far shrink and loosen that fatal hæmorrhage can take place. The elucidation of the question of blame in cases of fatal hæmorrhage from the umbilical cord is of special importance from a medico-legal point of view, and sometimes very difficult. The medical witness may be asked: Is the omission on the part of the mother to tie the cord from ignorance or from design, or in consequence of thoughtless want of preparation for her confinement? Secondly, in case the cord has been tied and has become loose, so that fatal hæmorrhage has taken place, has the midwife been guilty of causing death by criminal negligence, or of proceedings against the security of life? Views on these points are divided. Hofmann (1) states with emphasis that proof that omission to tie the cord has been intentional cannot be established, as we cannot prove that primaparæ, who are chiefly concerned, have any knowledge of this manipulation. Caspar-Liman take the view that in a case of the loosening of a cord that has been tied, the midwife should not be blamed without further information. Here an opinion would be arrived at from the surrounding circumstances as to intention or not. Thus Dittrich (55) (Aerz. Sachverst.-Zeit., 1897, 43 and 44) mentions a case of fatal hæmorrhage from the cord in which from the circumstances design could be excluded: A girl was going to the hospital in company with other people to be confined, when labour took place in the railway carriage; she severed the cord ignorantly, and wrapped several turns of a bandage round the stump. The child died of hæmorrhage. Between the cord and the ligature a thick sound could easily be passed. Beckert, who has recently interested himself with the question of blame in cases of fatal hæmorrhage from the umbilical cord (Zeitsch. f. Med. Beamte, 1899, S. 569), reports a case in which a midwife escaped conviction through difference in opinion amongst the medical witnesses, and as amongst the published cases he has met with only two convictions he is of opinion that the witnesses have been too lenient, being afraid of the consequences that might follow a conviction. He would have a charge made in every case in fatal hæmorrhage from the ligatured cord; the midwife has a great responsibility, as such hæmorrhages can be avoided in every case by careful and conscientious tying of the cord. In any case the question of blame where fatal hæmorrhage takes place when the cord has been tied has not yet been satisfactorily settled.

A child may also bleed to death from the cord during birth in cases of insertio velamentosa, when the advancing part of the child lacerates the velamentum. Volland (53) has collected 15 such cases from literature. Death may also take place from tearing of the cord when it is too short. Further, when there is a common placenta, a twin may bleed to death after the birth of the first one if its cord is not tied doubly (Sachs).

Besides death from bleeding from the cord, fatal hæmorrhage may also take place from injuries and ruptures occurring during labour, whether intentional or unintentional, along with proper or improper expert assistance, and whether the organs are healthy or diseased. To this category belong: Fatal hæmorrhage from tearing out of limbs, perforation, morcellement, rupture of blood vessels (particularly cerebral hæmorrhages), rupture of organs (the liver, spleen, intestines), fatal bleeding from parenchymatous organs.

It is to be noted that bruises and ecchymoses appear on the tumours of the head, buttocks, and shoulder, but they do not fall under this category. As consequences of obstetric operations, ruptures of the liver and spleen, for example, have been observed. Körber (St. Petersb. med. Wochenschr., 1892, No. 51) relates a case in which rupture of the liver occurred as a result of swinging the child in the way recommended by Schultze in cases of suspended animation. The question of blame in cases of rupture of organs is frequently very difficult from a medico-legal point of view. It has to be ascertained (Geill) whether the ruptures of organs found after death really took place during birth—*i.e.*, whether they were produced during spontaneous labour, under special circumstances (lingering labour from irregular presentation, contracted pelvis, rigidity of the soft parts), by assistance given by the mother herself, by the obstetrician in attempts to restore animation in a child apparently stillborn, by ignorant treatment of a child born alive (rupture of bowel by enemata), by infanticide, spontaneous rupture (of the spleen), by improper management of the stillborn child, or by any other cause. Dittrich (57) is of opinion that as manipulations that are to be looked upon as proper are carried out in normal labour also, it may be properly assumed that ruptures of internal organs may occur during labour, in which all mechanical violence independent of that of the maternal organism can be excluded. Kratter (71) concedes this as regards ruptures of organs, but not for hæmatomata of internal organs. In my opinion it appears certain that every case must be examined as to whether the force employed by the obstetrician or the midwife was necessary, or whether it was more than was allowable. Fatal hæmorrhage from ritual circumcision in cases of hemophilia is to be mentioned.

Fatal hæmorrhage from the female genital parts occurs from solution of continuity in the region of the clitoris, from wounds of the vagina from coitus, from wounds of the uterus during pregnancy, and in connection with labour. Cases of fatal hæmorrhage from the region of the clitoris, in which parenchymatous bleeding from the corpora cavernosa clitoridis may be fatal, as already mentioned, are rare. Niemann (Henke's Zeitsch., Bd. 392, S. 310, quoted from Hofmann) reports the intentional killing of a woman by a cut in the external genital parts.

More frequent, and more difficult to decide from a medico-legal point of view, are fatal hæmorrhages from wounds of the vagina from coitus. From statistics collected by Neugebauer (Monatschr. f. Geburtshilfe u. Gyn., 1899, IX., S. 22, iu. 289), out of 157 observations, there were 22 cases of fatal hæmorrhage. As to whether the wounds were produced simply by manipulations during coitus, opinions differed. Caspar-Liman's collection shows only cases in which the injuries were caused by the introduction of the finger or instruments. Maschka denies the occurrence from coitus, and explains five cases of wounding the vagina by the forcible use of the fingers. Hofmann concedes the possibility of such an occurrence, and attributes it to the brutality of the man, and want of proportion between the man's penis and the vagina. Mennicke (62), from his own observations, comes to the conclusion that the possibility of lacerations of the vagina occurring sub coitu cannot be completely excluded, as they were formerly, when some of the following predisposing causes are present: Drunkenness and the use of brutal force on the part of the man, a peculiar position during the act, want of proportion between the size of the penis and that of the vagina (for example, attempted rape of little girls); on the part of the female, status infantilis of the genital parts, climacteric age, antecedent gynæcological operations (colporrhaphy operations on the perineum). Mennicke relates a case in which the hostess of an inn, aged 55, died suddenly in the night, although she had been quite well the evening before; the husband had the reputation of being brutal and of leading a loose life. The autopsy revealed laceration of the vagina, and death from hæmorrhage. The medico-legal opinion agreed with the superior opinion of a professor, that the laceration might have been produced by coitus, and consequently not necessarily by another injury which was not excluded. Wichmann (63) (Aerztl. Sachverst. Zeit., 1900, No. 4, S. 67), reports on a case of laceration of the vagina, with subsequent fatal hæmorrhage from intercourse with a factory girl who was in the ninth month of pregnancy, and after inquiry into the case, comes to the same conclusion as Mennicke. Warmann (66) (Zur ætiologie u. forens. Bedeutungder Scheidenruptur, Zentralbl. f. Chirurgie, No. 24, 1897) finds the cause of rupture of the vagina, not in the disproportion between the size of the penis and that of the vagina, nor in too little power of resistance, nor in the altogether too stormy intercourse on the part of the man alone, but too much vigour on the woman's part, and maintains that when the woman strives against the act, rupture of the posterior wall of the vagina is impossible; such ruptures are not consistent with rape.

In my opinion deaths of this kind must from a medico-legal point of view be judged individually, not only as regards the autopsy, but taking in all the accompanying circumstances (see Mennicke's case); no general rule can be laid down concerning them.

Fatal hæmorrhage may also take place from rupture of the fœtal sac in ectopic gestation. The rupture is spontaneous as a physiological necessity, or from injury, which may be only very slight, as the fœtal sac has but little resisting power. These cases are of importance forensically, when an injury that might be the cause of the rupture has preceded it, whether the rupture is spontaneous or not. It is naturally difficult to arrive at a decision.

During labour fatal hæmorrhage may take place from wounds of the genital passages—ostium vaginæ (especially the region of the clitoris), vagina, uterus (cervix and fundus)—which may be caused naturally from want of proportion between the fœtus and the maternal parts, or from medical assistance being omitted or improperly rendered (Sachs). Here it has to be determined forensically whether the person responsible for the course of the labour (physician or midwife) had rendered the assistance demanded in a skilful manner, and kept the patient sufficiently long under observation after the completion of labour, whether she has been left too soon, and that whether thereby the aid that was demanded could not be rendered.

Fatal hæmorrhage from rupture of the uterus is of special importance. According to Schroeder, rupture of the uterus occurs during pregnancy from the third month on, later on more frequently, but upon the whole very rarely from any considerable crushing. Any force acting from before backwards against the vertebral column is more likely to be followed by rupture than one acting from the side; spontaneous ruptures during pregnancy are very rare. It must be assumed that some congenital or acquired thinness or softness of the uterine walls (Cæsarean section in a previous pregnancy, or softening from inflammation) is necessary for a rupture to take place. Rupture can then take place from slight causes, lifting a weight, a jump, a push, a fall, a cough, vomiting, or any other strain of the abdominal walls, or even without any apparent cause. The point of rupture—in contrast to those occurring in partu—is regularly in the fundus or at least in the adjacent parts (Schroeder). Jellinghaus (68) (Archiv. f. Gynækol., Bd. 54, H. 1) relates a case of rupture from thinning of the muscular walls. Ruptures of the uterus may occur spontaneously during labour, or they may be favoured by the pathological conditions mentioned, if when any hindrance to the passage of the child occurs—abnormal presentation, normal presentation, but contracted pelvis, hydrocephalic head of the child, and the lower segment of the uterus is over stretched, so that it tears; after such an event fatal hæmorrhage frequently takes place.

Such cases may become the subject of medico-legal inquiry if improper methods of treatment have been taken by the medical attendant or midwife, introducing the hand too far in, for instance, and thus contributing to the rupture. It will mostly be very difficult to decide whether a rupture has been unavoidable and would have taken place from the pains alone, or whether the fault lay with the medical attendant. Here also the circumstances may prove of value in arriving at a decision. In my earlier years of practical work I was called to the assistance of a colleague in a difficult case of labour. As I made my appearance the patient had just died, whilst the surgeon was rendering assistance in a case of rupture of the uterus and subsequent fatal hæmorrhage. No medico-legal inquiry took place, as the known good position of the medical man in question excluded any question of incompetence. The discovery of a morbid condition of the uterine muscles makes the diagnosis more simple. Heydrich (70) (Centralbl. f. Gynækol., 1897, No. 20) reports on a rare case, important from a medico-legal point of view, in which a very pendulous abdomen was the cause of the rupture, in consequence of which the posterior wall of the uterus was greatly stretched and rubbed through by the advancing head. Much more can be done from a medico-legal point of view in those numerous cases in which death results from injuries of the female genital organs that have been brought about by too rough or careless handling, or those fatal accidents when the treatment on the part of the persons responsible has been quite correct (v. Sachs).

Medico-legal records of errors in the performance of obstetric operations by surgeons, midwives, and quacks are very numerous. Penetration of the vagina and uterus by instruments are the most frequent occurrences. Injuries of the bowels in connection with rupture of the uterus also occur. As a curiosity a case quoted in the "Vierteljahrsch. f. gerichtl. Med., Bd. 21, S. 80, may be mentioned, in which the whole uterus was torn away in removing the placenta. In these cases, mostly of grave injury caused by violent manipulations, fatal hæmorrhage is frequent. The question of blame is usually not difficult to decide. After labour fatal hæmorrhage may occur from atony of the uterus, and it may be the subject of medico-legal inquiry if the woman confined has been left too soon after delivery, or if it can be proved that the person responsible failed to make use of the usual internal remedies or manipulations, although it must be remarked that death may follow in spite of their employment. Secondly, if the placenta has been separated by the hand and a portion left behind, proof of blame in such cases is not difficult to establish. Thus Mair (85) mentions a case of fatal hæmorrhage from atony of the uterus, where the midwife removed the after-birth without satisfying herself that the uterus had contracted. The blame might easily have been fixed upon her in such a case.

The Relation of Death from Hæmorrhage to the Accident Insurance Law and to the Civil Code.

The forensic surgeon may be placed in a position in which, in cases of death from hæmorrhages of persons who are insured against accidents, of having to decide whether the death has been caused by the accident whilst at work, or whether it has been spontaneous as the natural outcome of an illness. On this decision hangs the right of the heirs to the insurance moneys; further, whether the death in question was connected causally with an earlier accident or an earlier injury or not. The right to compensation for injury on the part of survivors, according to par. 844 of the Civil Code, may hang on this decision. The cases belonging to this class are not numerous, so that there is a scarcity of material for reference. In general these questions are difficult to decide. In an earlier place a case reported by Danzer has already been mentioned (28), where proof could not be adduced that death was due to an accident that occurred seven years before. But even when it is only a matter of days between the injury and death, it is not always possible to establish the connection. In Friedrich, s. Blättern of 1852, a case is reported where a woman in stealing wood was struck with a stick. Four days afterwards she died from hæmorrhage from an aneurysm (it was probably an aneurysm of the aorta, but this is not shown in the proceedings). The connection between the injury and the death could only be established as probable. In the Aerztlich. Sachverständ. Zeit., 1898, No. 8, S. 167, a case is mentioned of sudden death from bleeding from a gastric ulcer whilst at work, in which the trade society objected to pay the claims on the ground that the death was the natural outcome of an advanced degree of disease of the stomach. In a trial, however, they were held liable on the ground that on the day on which the deceased met her death the work was particularly heavy, that this caused unusual action of the heart, and that the hæmorrhage was due to that. In another place (77) a case of hæmorrhage from the lungs is mentioned that occurred four days after an accident in a man who was suffering from intestinal tubercle, the deceased striking his right side against a wooden corner in falling into a filter pit. The connection between the accident and the death in this case was confirmed by the medico-legal expert, although denied by the medical officer to the man's trade society, and the money claimed was paid. In another case (76) the connection between fatal hæmorrhage from the lungs and the performance of work—lifting a heavy chest—was denied for want of sufficient evidence that it was due to any one distinct act. Markwald (74) mentions the following case: A joiner whilst at work, sawing a beam, was taken suddenly ill with violent pain, vomiting, spitting of blood, inability to move or speak, and died in a few hours. Three minutes before commencing to saw he had lifted a heavy beam. The autopsy showed arteriosclerotic changes in the aorta, free hæmorrhage, an aneurysm that by eating through the bronchial vein had allowed the passage of blood into the bronchus. Markwald denied any connection between the bleeding and the sawing, as there was no proof that this, the proper work of the joiner, was the cause of the bleeding. He gave a warning against a too wide-reaching humanitarianism, and demanded only a searching, scientific criticism of the cases and opinions, lest at a not distant date every disease should be looked on as the result of an accident. From this small number of examples it will be seen that no general principles can be laid down for the treatment of these questions; each case must be decided by itself.

The results of this work may be summed up in the following conclusions:—

(1) The usual course of death from hæmorrhage is this: that immediately on the occurrence of a spontaneous or traumatic solution of continuity of the vascular system internal or external hæmorrhage takes place, and, hindered by nothing, continues uninterruptedly until in a few minutes death takes place from cerebral anæmia.

(2) The principal deviations from the usual course are: interruptions in the course of the bleeding (death

from secondary hæmorrhage, late hæmorrhage), as well as complications through the secondary effects of the bleeding (pressure on the brain, heart, lungs, blocking of the air passages, air embolism).

(3) The deviations from the usual course in the various injuries that may be followed by fatal hæmorrhage show themselves in the following manner:—

(*a*) In fatal hæmorrhages from wounds of the heart all the deviations mentioned may occur.

(*b*) Fatal hæmorrhage from injuries of the great blood vessels deviate from the usual course in proportion to the smallness of diameter of the vessel injured.

(*c*) In death from hæmorrhage from rupture of organs, the mode of origin of the rupture was the first point in the medico-legal inquiry whether the rupture was due to traumatism or whether it was the spontaneous result of some disease of the organ, or whether both modes came into consideration, and, if so, in what relation did the trauma stand to the disease.

(4) The diagnosis of death from hæmorrhage is based on the proof of a solution of continuity in the vascular system, of hæmorrhage having taken place, and of a high degree of anæmia of the body generally when not decomposed, the evidence of other causes of death not being discoverable. In these cases the diagnosis is not difficult on post-mortem examination.

(5) If the body is decomposed, or if there is evidence of other causes, the diagnosis is more difficult, and circumstantial evidence must be appealed to.

(6) For the purpose of distinguishing death from hæmorrhage from allied forms—injury of vital organs—it is an advantage to distinguish between simple and complicated deaths from hæmorrhage:—

(*a*) It is simple when due to loss of blood and nothing else.

(*b*) Complicated when death results from the secondary effects of the bleeding (paralysis from pressure on the brain, heart, lungs, blocking of the respiratory passages by blood, air embolism).

Note.—Those cases are allied to complicated death from hæmorrhage where the bleeding is from a body in which there is a deficient supply of oxygen from a morbid condition of the heart or lungs. Here paralysis of the brain and death will come on earlier, so that absence of blood in the organs may not be as complete as under ordinary conditions. Further, hæmorrhage that would do no harm under ordinary circumstances might be fatal (as in abortions, for example). This statement can at present be given as hypothetical, as no practical examples are so far recorded.

(7) Principles regarding the determination of fatal hæmorrhage from the umbilical cord in infants, when it has been tied, but become loose, cannot yet be laid down.

(8) The determination of the origination of injuries of the vagina (*sub coitu*) that lead to fatal hæmorrhages is, for want of agreement amongst inquirers, very difficult, and cannot be reached without a knowledge of the circumstances.

(9) The causal connection between a death from hæmorrhage and an earlier injury or accident when there is a question of compensation on the part of heirs, or of an accident pension, is frequently impossible, especially when a considerable time has elapsed between the injury and death.

OUT-PATIENTS' ROOM

ROYAL FREE HOSPITAL.

Epithelioma of the Cheek.—New Operation.

By J. Cunning, M.B., F.R.C.S.

Amongst the out-patients was a man, æt. 56, who complained of soreness of the inner side of the cheek, which came on, he said, a fortnight previously. On examination an ulcer was discovered, in extent about the size of a florin, reaching from close to the angle of the mouth backwards to about the second molar tooth. The ulcer was deeply excavated, with irregular raised edges and a nodular base; the whole ulcer and its margins were very hard and not specially tender; there was a dirty, fœtid discharge from it. In the submaxillary region two small hard glands could be felt. The diagnosis, Mr. Cunning said, was the first point to be established. Ulcers of this type were usually epithelioma; the other ulcers which had to be considered were primary sores and dental ulcers. Dental ulcers could be excluded in this case, for they were always in the neighbourhood of a ragged tooth, and were never of a deeply excavated character. A primary sore might look very like an epithelioma, but as the patient's age was an ordinary one for epithelioma, which is a more common disease than primary sore in the mouth, one would be entitled to assume that this is more likely to be an epithelioma than a manifestation of syphilis. The glands under the jaw would be enlarged in either case, so that they could not be looked upon as helping the diagnosis in either way. There were two ways, he remarked, of settling this point: one was by giving mercury, the other by removing a piece for microscopical examination. The latter of the two methods, he thought, was the better, as it involved no delay. With regard to treatment, Mr. Cunning pointed out that, assuming this was an epithelioma, it could be completely removed, as it was quite free from the jaws; it would mean that a large area of the cheek, certainly as much as the palm of the hand, would have to be taken away. This meant that a very wide gap would have to be filled in. The plan he had devised for doing this was to begin by turning up a large flap covering the submaxillary triangle, and removing the submaxillary and salivary glands from this area, before touching the cheek. The cheek would next be excised. Then the flap raised from the submaxillary triangle would be divided at the junction of its posterior and middle thirds; the anterior section of this flap would then be twisted upwards and fixed to the upper edge of the gap in the cheek close to the angle at which the remainder of the lips would be stitched to one another; the posterior third of the flap would next be pulled forwards and upwards, and stitched not only to the remainder of the upper portion of the gap in the cheek, but also to what is now the posterior edge of the twisted-up anterior portion of the flap. It is now found that a very good new cheek has been formed, which can be covered by a beard in a male patient. It finally only remains to cover the bare area in the situation of the submaxillary triangle; this can be done quite easily by under-cutting the skin of the neck, sliding it upwards, and stitching it to the skin at the level of the lower jaw. In a previous case in which this plan of operation devised by Mr. Cunning had been carried out by him, a very large gap had been filled up with surprising ease, and when the patient returned two months after discharge from the hospital, having in the meantime grown a beard, it was almost impossible to tell that an operation had been done, therefore Mr. Cunning now proposed to perform a similar operation on the present patient.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Radical Cure of Hydrocele.—Mr. Willmott Evans operated on a man, æt. 28, who had been admitted for chronic hydrocele. For some five or six years the patient had suffered from a hydrocele of the right side; it had been tapped many times and liquids had been injected in order to affect a cure, but without avail; the fluid had always re-collected. The presence of the hydrocele was troublesome to him, and he was anxious to have a radical cure. When the patient was anæsthetised the surface of the scrotum was well scrubbed with soap and antiseptics. An incision was then made the whole length of the swelling and extending down to the tunica vaginalis; this was laid open, the contents were evacuated, and the greater part of the parietal portion of the tunica was removed; it was somewhat thickened, doubtlessly owing to the previous treatment. The edges of the wound were then brought together with catgut sutures, and a dressing was applied. Mr. Evans said that the question of the best method of treatment depended greatly on the age of the patient: in small children hydrocele was common, but he had never seen a case in a young child in which even tapping was required, for, according to his experience, cases such as these always got well without any form of operation. In the aged tapping was all that it was advisable to do, at least in the majority of cases, for such patients required to be tapped only once or twice a year, and it was surely better in such cases not to run the risk of a radical cure, slight though that risk might be; yet there were cases even amongst the old in which a radical operation was perfectly justifiable, but the patient must be in good general health and young for his years. During the middle period of life it occasionally happened that a single tapping was sufficient to cure a hydrocele, or perhaps the fluid might not re-collect after the second or third tapping; usually, however, it was not possible to cure a hydrocele simply by removing the fluid, and something more was required to be done. In many cases injections of certain liquids after tapping the sac led to a cure. Many liquids have been used for this purpose which are quite discarded now. At one time it was advocated to re-inject the fluid which had been withdrawn; port wine was also a favourite injection. At the present time there are only two liquids which are much used for injection in these cases; one is a weak solution of iodine, the other is carbolic acid. It is important in employing these liquids that the inner opening of the cannula should be definitely within the sac, otherwise the liquid is liable to escape into the loose connective tissue superficial to the tunica vaginalis, setting up a severe and painful, though aseptic, cellulitis. Whatever fluid is employed, the whole of it should be evacuated through the cannula. This method is sometimes successful; its mode of action is by no means certain. The cause of a persistent hydrocele is the excess of secretion of hydrocele fluid over the absorption. This may be produced in either of two ways: the amount secreted may be abnormally great or the power of absorption may be diminished. Even in a perfectly healthy tunica vaginalis fluid is always being secreted and always being absorbed. How the injection acts is not clear. At one time it was thought that the injection led to obliteration of the sac of the tunica vaginalis, but this certainly does not occur; probably the injection diminishes the secreting power of the lining epithelium without impairing the absorptive power.

The radical cure of hydrocele consists in the removal of part of the whole of the parietal layer. When this method was first introduced, after the tunica had been incised and more or less of it removed, the wound was plugged and allowed to granulate up from the bottom; in fact, sometimes an incision was simply made without any removal of the parietal tunic; the method was effective, but very tedious. It is far preferable to excise the whole of the parietal layer and to close the wound; no drainage is required. The theory of the method is this: By removal of the parietal tunic we diminish the secreting area by at least half, and sometimes by much more in cases where the sac has been much dilated; moreover, what remains of the cavity is made to communicate with the extensive subcutaneous tissue of the scrotum, all the interspaces of which communicate freely with the lymphatic system, so that its absorptive power is almost unlimited. The method is very satisfactory, but the utmost care must be taken to secure asepsis, and it is recognised that it is exceptionally difficult to render the skin of the scrotum aseptic. The higher the incision is made, the smoother the skin, and the less the chance of sepsis, and by turning the tunica vaginalis inside out, it is possible to excise its parietal layer through an incision commencing immediately below the pubic crest.

The wound healed by first intention except for one stitch abscess. No recurrence took place.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, NOVEMBER 1ST, 1907.

The President, Sir **HENRY SWANZY**, in the Chair.

SOME UNUSUAL ABDOMINAL CASES.

Mr. **GRAVES STOKER** read a paper in which he gave the clinical history of a number of interesting abdominal cases. In one of these, a woman, who had suffered for a number of years from almost incessant vomiting and extreme emaciation, and who had been diagnosed by a late distinguished Dublin surgeon as having malignant disease of the stomach, obtained complete relief from her symptoms after an exploratory laparotomy in which the stomach was found to be quite normal. In another case, apparently of hydronephrosis, the patient, a woman, had the power of emptying the sac, whose capacity was several pints, more or less at will.

Dr. **WHEELER** said all the cases showed points of interest; and spoke with approval of the results obtained through the adoption of the method of continual saline injection as practised by Murphy, of Chicago. The theory advanced by Murphy to explain the great improvement in his results was that the lymphatic circulation in the abdomen was reversed, and the saline pouring in prevented the toxins of pus going the other way.

A CASE OF LIGATURE OF THE INNOMINATE ARTERY.

Sir **THOMAS MYLES** read his communication on this subject. In the course of his extremely interesting paper he described the symptoms and signs presented by a male patient, aged twenty-nine years, who suffered from a right sub-clavian aneurysm. He gave the reasons why he was led to reject treatment by Symes' method of opening the sac, followed by ligature of the artery on the proximal and distal sides, and also the treatment by distal ligature alone in favour of ligature of the innominate artery. The chief of these was that the most frequent cause of failure in previous attempts—namely, secondary hæmorrhage induced by sepsis—could now almost certainly be prevented. Most of these operations had been carried out in the pre-antiseptic era, while Mr. Coppinger's case, which was brilliantly successful, was performed with strict antiseptic precautions. He then discussed the methods of approach of the artery, finally selecting a median incision in the lower part of the neck, the ligature being accomplished without either division of the sterno-mastoid, resection of the inner end of the clavicle, or trephining the sternum. In addition to securing the innominate he placed a double ligature on the right common carotid dividing the artery between. He expressed the opinion that in carrying out this step he left too short a distance between the two ligatures, and that to this the failure of the operation was due. He then detailed the subsequent progress of the case, which was at first very favourable. The wound healed by the first intention, the pain caused by the aneurysm disappeared, and the patient felt very well. The pulsation in the aneurysm, however, persisted. About ten days after the operation a large subcutaneous hæmorrhage occurred, which was treated by reopening the wound and securing the bleeding vessel, which could not be identified. Subsequent hæmorrhages, however, took place necessitating further operations which for a time checked the bleeding. The wound now began to suppurate, the hæmorrhages continued to take place, and, finally, the patient died about a month after the first operation. The *post-mortem* examination showed that the source of hæmorrhage was the carotid artery from which one of the ligatures had slipped.

Mr. **WILLIAM TAYLOR** said there were, after all, only two reasons why success should not attend the effort to ligature the innominate artery—first, failure in the establishment of the anastomotic circulation of the brain; and, second, sepsis. One ought to be able to control the latter, and, therefore, should be able to control the secondary hæmorrhage. Yet they all knew how possible it was for some septic infection to creep in, and in Sir Thomas Myles' case it was just possible that there may have been some source of infection in the bottom of the wound in the deep structures. Barwell had drawn attention to the fact that death in such cases almost invariably arose from secondary hæmorrhage, and had stated that if ever he came to ligature the innominate artery he would ligature the vertebral artery as well as the innominate and carotid.

Sir **THOMAS MYLES**, in replying, stated his belief that the cause of failure was that the ligature on the common carotid had slipped.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

MEETING HELD THURSDAY, NOVEMBER 14TH, 1907.

Mr. R. **MARCUS GUNN**, F.R.C.S., President, in the Chair.

Mr. J. **HERBERT FISHER** read a paper on some cases of

INTERSTITIAL KERATITIS FROM ACQUIRED SYPHILIS.

Before reading notes of four cases which he had personally observed, he expressed his surprise that so few instances of interstitial keratitis from acquired syphilis had been brought before the Society: this was the more regrettable seeing that Mr. Jonathan Hutchinson, when vacating the Presidential chair, had especially directed the attention of members to this subject as one upon which information might usefully be collected. The text-books dismissed the subject with very brief reference, and gave no authoritative statements as to frequency, date of onset, severity, and prognosis of the disease. After reading notes of his four cases, and alluding to one of corneal inflammation which rapidly followed the primary inoculation of syphilis on the lower eyelid, Mr. Fisher expressed his opinion that interstitial keratitis from acquired syphilis was generally a tertiary manifestation: that it appeared usually to attack only one eye, and that the infiltration frequently limited itself to a portion only of the cornea—that the keratitis, as far as it went, was identical in clinical appearances with that due to inherited disease, and that the statement which had been made by Nuel, that it was usually secondary to irido-choroiditis, was by no means universally accurate. Mr. Fisher further read notes of a case of interstitial keratitis in the child of a mother who had herself inherited syphilis, and who had in consequence suffered from kerato-iritis, with choroiditis and deafness. The question of the transmission of syphilis to the third generation was raised upon this case: assuming the husband of a woman, who had inherited syphilis, to have acquired syphilis, the point was raised whether she was more or less likely than a wife free from inherited taint to bear syphilitic children to him. Other practical points of discussion were raised, and members were invited to contribute their experiences, in hope that evidence might in time be obtained which would be of guidance both to ophthalmic and general surgeons, in answering the questions which might be addressed to them as to the advisability of marriage by patients who were the subjects either of inherited or of acquired syphilis.

Mr. **Thomson Henderson** (Nottingham) read a paper on the

ANATOMY OF THE SO-CALLED LIGAMENTUM PECTINATUM IRIDIS, AND ITS BEARING ON THE PHYSIOLOGY AND PATHOLOGY OF THE EYE,

a full abstract of which will be found under the heading of "Original Papers," page 543.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Clinical Evening.

Meeting held November 1st, 1907.

The President, Mr. **Richard Lake**, F.R.C.S., in the Chair.

The following patients were shown:—

Dr. **Arthur Saunders**.—A boy, æt. 6, with chronic disseminated myelitis. The patient was attacked with scarlet fever a year ago, this was followed a fortnight later by the onset of paraplegia with anæsthesia of the legs and lower part of the trunk. His condition has remained practically stationary since that time.

Dr. F. S. **Palmer**.—A boy, æt. 15. Primary progressive myopathy of the facio-scapulo-humeral type. No nervous disease in family. Five brothers and two sisters living and well. Patient was quite well until 18 months ago, when he first complained of fatigue and weakness in arms and shoulders, at the same time it was noticed that the facial muscles were weak. The wasting and weakness have been steadily progressive.

Dr. **Blair**.—(1) A youth with congenital absence of iris. In the right eye the iris is entirely absent, and the lens is deficient at its lower edge, and has a small anterior pyramidal cataract. The left eye has practically the same defects. His father and sister have somewhat similar congenital anomalies of the iris. (2) A case of misplaced pupils.

Dr. **Seymour Taylor**.—Man, æt. 34. Perforation of aortic valve. The patient had lead colic on two occasions, and has a typical blue line on the gums. While lifting a heavy weight experienced severe pain in upper zone of chest, choking sensation in throat, and faintness. There is a diastolic thrill all over the front of the chest, and a loud diastolic musical murmur is heard all over the chest, back, and front; also over the upper half of each humerus.

Mr. **McAdam Eccles**.—Man, æt. 45. Charcot's disease of left knee. Signs of locomotor ataxy for three years. The pupil reaction is only present on the left side. The joint became largely distended with fluid in three days and without pain. Fifteen ounces of fluid were aspirated from the joint, and a plaster case applied. While this was on no re-collection of fluid took place, but on its removal the joint became distended in the same time as before.

Mr. **Aslett Baldwin**.—(1) Female, æt. 29. A case of excision of the rectum for carcinoma by an abdomino-anal method. Admitted with complete intestinal obstruction of 10 days' duration. Colotomy was performed. Later the abdomen was reopened and the attachments of the rectum divided as high as the sigmoid flexure. The anus dilated, and the bowel and growth forced out through the anus, forming an intussusception. This was cut off externally, and the bowel united by circular suture and returned. The sigmoid is attached a short distance above the anus. The patient has perfect control and normal action of bowels. (2) Man. Lengthening of left leg and extensive nævus of left half of body. A venous nævus occupies the left side of the trunk and most of the left thigh, leg and foot. The left leg is 2½ inches longer than the right, and the left foot is ½ inch longer, but the left calf measures 11½ inches in circumference, whereas the right measures 13 inches. Varicose veins are also present in the left leg. (3) Man, æt. 30. Carcinoma of right breast. Noticed lump about 10 months, which has been ulcerated about a month. Two secondary growths in skin near the primary one, numerous hard, enlarged glands in axilla. A microscopical section of one of the secondary growths showed typical scirrhus carcinoma. (4) Girl, æt. 4. Tumour of scapula, etc. The enlargement of the right scapula was noticed two months ago. The lower end of the right fibula is markedly thickened, and nodules can be felt on the metacarpal bones and phalanges of the right hand. There appears to be no pain or tenderness.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held November 7th, 1907.

Mr. T. H. **Bickerton**, Vice-President, in the Chair.

AN UNUSUAL CASE OF ATAXIA.

Dr. F. J. S. **Heaney** described and showed a case of ataxia presenting an unusual combination of symptoms and some difficulty in diagnosis. The patient, a painter, æt. 52, developed a spinal curvature in the dorso-lumbar region when two years old, presumably as the result of caries. The curvature had caused no symptoms, and the patient had never had syphilis. Ataxia, Rombergism, absence of knee-jerks, numbness of the feet, and diminution of pressure sense over the lower extremities appeared six months ago. There were no Argyll-Robertson pupil phenomena, no lighting pains, and no interference with the fields of vision or with cutaneous sensation. Muscle power and sphincters were normal. Cutaneous reflexes were normal, the plantar being flexor in type. The only alterations in his condition in the last six months were a transient left ankle clonus and a recent slight return of right knee-jerk. The differential diagnosis between tabes, combined system degeneration, and recurrence of spinal caries with focal myelitis and posterior column degeneration was discussed, Dr. Heaney deciding in favour of the last diagnosis.

Dr. T. R. **Bradshaw** said that the unusual feature in the case was the temporary restoration of the knee-jerk. The present condition, apart from the history, would justify a diagnosis of tabes, and often in cases which were obviously specific, no history of infection could be obtained. The Argyll-Robertson pupil was only observed in about 80 per cent. of cases of tabes. If the knee-jerks returned again, he would suggest that the ataxia was due to a neuritis possibly caused by lead (there was a history of lead colic), producing a condition analogous to alcoholic pseudo-tabes.

Mr. R. J. **Hamilton** gave a short description of Kroenlein's operation, and showed a successful case in which this operation had been done for a tumour surrounding the optic nerve and causing considerable proptosis. The tumour was a spindle-celled sarcoma, and measured 1⅓ by 1⅛ inches. The results were—an eye with good vision, perfectly free movements, and very little scarring in the temporal region, the seat of the incision.

Dr. K. **Grossmann** remembered being consulted by the same patient, who had been told at an eye hospital that the proptosis was due to one-sided exophthalmos, and recommending an operation. At that time a hard tumour could be felt between the lower outer orbital margin and the eyeball, and it was an open question whether it could not have been removed by a simple incision along the lower margin of the orbit. He considered that Kroenlein's operation was suitable for cases of retro-ocular tumour which could not be removed from the front without severe damage to the eyeball. Dr. Grossmann described some of the modifications of the operation.

Dr. **Stoopes** and Mr. E. M. **Stockdale** also spoke.

Mr. C. **Thurstan Holland** showed, and explained the working of, the Levy-Dorn Orthodiagraph, which had been in use at the Royal Infirmary since last June. This pattern allowed of the patient being examined either lying down, standing, or sitting. It was pointed out that the lying down position was undoubtedly the best, and for this Mr. Holland had found the instrument devised by Professor Moritz the more reliable and the easier to work. Tracings of hearts at different ages were passed round. Mr. David Morgan gave his experience of this and other methods.

Mr. Douglas-Crawford read a note upon two cases associated with elongated meso-cæcum: (1) Volvulus of the cæcum in a woman, æt. 39, the torsioned mass lying above the umbilicus on the left side. Early operation resulted in a successful untwisting of the mass, and the patient made a good recovery. (2) Malignant cæcum in a man of 35. The "lump" lay in the right lumbar region, moved freely with respiration passing up behind the liver, and down as far as the iliac crest, but not reaching the iliac fossa. The mass was excised, and later the fæcal fistula closed, but only after a lateral anastomosis had been effected between the ileum and the transverse colon. The patient was perfectly well one year after the excision of the growth.

Dr. F. M. Gardner-Medwin gave a demonstration of the ROTH-DRAGER OXYGEN-CHLOROFORM APPARATUS, with a short note and report on 25 cases. The advantages of the apparatus were—regular doses of known quantity and the easy control of the concentration of atmosphere. It was compared with other mechanical apparatus, and stated to be of great value in serious cases when ether narcosis was contra-indicated. The cases reported were all serious ones and mostly of long duration. They all showed complete absence of cyanosis, and in cases where ether had caused profuse salivation and venous engorgement the apparatus was particularly useful. One case of empyema, although the patient was unable to lie down and coughed up pus continually, after a few breaths of free oxygen easily bore the gradual exhibition of chloroform, and was able to lie down and take the anæsthetic quite easily.

Dr. Fingland said that the method of administering oxygen with chloroform was suggested by Mr. T. G. H. Nicholson, of Liverpool, some years ago, and that his apparatus was figured in the *British Medical Journal* in 1896. Mr. Nicholson's theory was that the lessened blood pressure produced by chloroform, and the corresponding slowing of respiration and circulation, interfered with the elimination of carbonic acid and caused its accumulation as an active toxine, which condition would be prevented by the administration of oxygen with the chloroform vapour. But Dr. Fingland was of opinion that the effect of the admixture of oxygen with the chloroform would be to inhibit to some extent the combination of chloroform with the red corpuscles of the blood, and by this means remove the real danger of chloroform narcosis. After referring in detail to several points of the Roth-Drager apparatus, he suggested the more extensive use of ether by the Rochester method of administration as possessing the advantages of a safe and natural anæsthesia.

Dr. F. W. Bailey thought that the length of time required for induction, and the difficulty which would be probably met with in the case of full-blooded, strong workmen, and the complications of the apparatus, would prevent it coming into general use in hospital practice, while its cumbersomeness and want of portability would make it difficult to use in private practice, and furthermore, he saw difficulties in the way of using it for mouth operations. The administration of anæsthetics could not be reduced to "rule of thumb."

Mr. G. P. Newbolt said Dr. Medwin had used the apparatus many times in major operations on patients under his care. He was convinced that it was a most efficient way of administering chloroform. Patients appeared to suffer less from shock, and their condition was better than when chloroform was given by one of the usual methods. He was not certain whether the oxygen caused some slight bronchial irritation, and suggested that it should be warmed before being inhaled.

The Public Health Committee of Leith Town Council, at a meeting on November 12th, agreed to recommend the Council at their January meeting to adopt the new Notification of Births Act. They also resolved to ask a remit from the Town Council to introduce a system of supplying Buddeised milk.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 17th, 1907.

BRONCHO-PNEUMONIA IN YOUNG CHILDREN.

Broncho-pneumonia affects particularly scrofulous children or those with some hereditary taint, but also children recovering from some secondary affections as grippe, measles, diphtheria, whooping cough, and is particularly prevalent in the winter season. Overcrowding in schools exercises a real epidemic influence where the dust carries, not a specific microbe as has been proved, but variable micro-organisms distinct from the agent of the initial cause. All kinds of germs are found, pneumococci, streptococci, baccilli of Friedlander, to which are added the septic flora of the buccal cavity and of the air inspired. Hence the necessity of careful antisepsy of the nasal fossæ and of the mouth, and the periodic ventilation of the school rooms.

The bases of the lungs are first affected; dry crepitating râles constitute the first signs, followed soon afterwards by murmur, at first soft, then loud and frequently surrounded with sibilant râles.

The dyspnœa is intense, the cough short and painful. Very young children do not expectorate, but those of two or three years expectorate mucus at the period of coction.

Antisepsy of the nasal fossæ and the mouth is always necessary. For the former, the following ointment should be introduced:—

Salophen, ½ dr.
Boric acid, ½ dr.
Menthol, 11 gr.
Vaseline, 1 oz.

While the mouth and throat should be sprayed with:—

Phensalyl, 10 gr.
Chloride of sodium, ½ dr.
Boiled water, 1 pint.

The patient should be isolated from other children, when possible, and kept in a warm room, and the air charged with the vapour of eucalyptus and thymol:—

Eucalyptus oil, 15 gr.
Menthol, 15 gr.
Thymol, 15 gr.
Ess. of lavender, 1 dr.
Tincture of tolu, 2 dr.
Proof spirit, 4 oz.

A teaspoonful in a saucepan of boiling water and covered with a funnel. Where this method cannot be employed, essence of turpentine poured on a plate placed near the bed of the child and renewed from time to time is good practice, as turpentine sends off ozone vapors.

Revulsives, such as cupping, blisters (carefully dressed with iodoform ointment), warm poultices powdered with mustard, are always indicated, but in very young children rubefacient friction with the following liniment should be preferred:—

Ess. of turpentine, 1 oz.
Liq. ammonia, ½ dr.
Lini sinapis co, 1 dr.
Lavender spirit, 2 oz.

Under five years of age, the lower extremities of the children should be enveloped in absorbent cotton, covered with impermeable tissue in order to provoke sudation of the limbs with consequent vaso-dilatation of the vessels.

Calomel, quinine, aspirin are indicated during the first few days, and the heart should be sustained with digitalis, rum, punch, etc. When expectoration appears it should be encouraged by

Antimonial wine, 20 drops.
Syrup of poppies, 1 dr.
Gum water, 4 oz.

A teaspoonful every two hours.

ARTIFICIAL ABSCESS.

Artificial pyogenesis, says Prof. Thiroloix, should always be regarded as an exceptional method reserved for the gravest cases, those that might be called "desperate." It should never be currently employed, as in the first place it provokes great pain, and, secondly, it requires during its development careful aseptic treatment.

When, in presence of acute or sub-acute septicæmia (without localised visceral suppuration), due to streptococcus, staphylococcus, or pneumococcus, and resulting from an attack of grippe, pneumonia, broncho-pneumonia, from scarlatina, typhoid fever, or puerperal injection, the first treatment should consist in injections of antistreptococcal serum or preparations of yeast. If this agent has no effect, intravenous injections of collargol should be tried:—

Collargol, 15 gr.
Sterilised water, 4 oz.

One drachm injected into the cephalic vein or one of the large superficial veins of the leg.

Subcutaneous injections of nucleinate of soda (1 gr. every six hours) have also a salutary effect.

If all this treatment seems of little avail, a last chance should be given to the patient by the creation of an artificial abscess. For this purpose the region selected for the abscess (flank, deltoid region, middle and external third of the thigh) should be disinfected by soap and water, followed by proof spirit and ether. With a sterilised hypodermic syringe, 20 drops of essence of turpentine are injected into the cellular tissue and the parts immediately covered with antiseptic gauze.

A few hours after the injection the patient complains of smart burning pain, and soon patches of inflammation appear, and the region becomes œdematous. This diffuse inflammation lasts one or two days, when the tumefaction becomes circumscribed, the pain disappears, and the abscess begins formation. The reaction can be either nil, moderate, or acute. Where it is nil, the prognosis is very grave, as it indicates that the infection is going to terminate fatally. The organism is not able to react to the solicitation of the chemical agent. Where the reaction is moderate, the abscess continues to slowly develop. In such cases it should not be opened too soon, and, above all, not until all unfavourable symptoms have disappeared. Perhaps the creation of another abscess may be necessary. In any case, subcutaneous injections of nucleinate of soda should be given as a general stimulant to the organism.

Acute reaction of artificial abscess is a very good sign, and renders the prognosis very favourable.

GERMANY.

Berlin, Nov. 17th, 1907.

The *Archiv. f. Klin. Chirurgie*, 83, I., contains a paper by Dr. Berger on

Injuries to the Abdomen by Blunt Force,

in which four cases of operation of special interest are related.

The first was a case of rupture of the spleen. A soldier, 19 years of age, fell out of bed, striking the left side of his body on the corner of a footstool. The general symptoms (great pallor, an anxious expression of face, difficult breathing, small frequent pulse) pointed to hæmorrhage into the abdominal cavity; the local symptoms (increased dulness in the splenic region that did not change on change of position, and abrasion of the skin over the ninth rib) pointed to the spleen as the source of it. The anæmia, which was rapidly increasing, demanded immediate operation. This, performed 24 hours after receipt of the injury, showed a rent in the spleen 8 cm. in length, reaching to the hilus, with blood still flowing from it. Plain signs of internal hæmorrhage had not shown themselves until within 12 hours of the injury. As the quickest and safest mode of treatment, ligature and extirpation of the injured organ were performed. In the after-treatment saline infusions were many times demanded and made use of. Eight weeks after the operation the patient was quite well, with the exception of some paleness, which the writer attributed to slowness in blood regeneration. No swelling of the lymph glands or of the thyroid was observed. The literature of cases hitherto published (241 cases) gave the mortality as 39 per cent (2) Traumatic cholecystitis. There were two cases of this. In the first case a man was thrown from a horse, dragged 50 yards, and received several kicks on the right side, after which a chronic cholecystitis developed. At first there was great pain without any objective symptom; later on the pain diminished, and at times ceased altogether. At last attacks came on with great pain in the region of the liver, vomiting, slight jaundice, and some fever. An operation, performed three months after the injury, showed cord-like adhesions between the omentum and the anterior abdominal wall, firm adhesions between the lower margin of the liver and the same wall, and the gall-bladder, which was free of stones, and was long, flaccid, and half-filled, was adherent to the colon. Cystotomy was performed after separation of the adhesions. Permanent closure of the fistula took place four months later.

In the second case a woman fell with her right side on to the edge of a water pail. The day after she felt a longish movable tumour in her right side, but felt well. On the second, symptoms of peritonitis appeared which indicated a serious condition. An operation showed the presence of gall-stones (17 in number), which, as they were formed into a firm conglomerate, had not up to then set up any irritation of the mucous membrane. It was only the injury caused by the fall in which the mucous membrane was bruised between the sharp edge of the pail and the gall-stones that permitted the invasion of bacteria to set up any injury. Here again cystotomy only was called for, and healing was complete 39 days after the operation.

The next was a tumour of the mesentery after an injury. This case proved fatal, but the surprising condition met with at the autopsy made it very interesting. A soldier, æt. 24, who had previously always been healthy, felt a violent stabbing pain in his right side as he sprang over a ditch, but did not make any complaint until four days afterwards. At first some tenderness on the right side of the abdomen, with slight resistance, gave rise to a suspicion of typhlitis. In the evening, after energetic bodily movement, there was considerable increase of pain, along with vomiting, and the following morning a tumour the size of a child's head was felt to the left of the umbilicus. Vomiting was present with meteorism, no flatus or stool passed, and the pain was extremely violent. On an operation being performed, a tumour of the mesentery was found that had been latent up to then, but which had got considerably larger through hæmorrhage into it. The tumour was a sarcoma. Drawn out over the tumour, flattened like a cord, and rather sharply kinked, ran the ureter, too much compressed to allow the urine to flow freely, so that the kidney was in a state of acute hydronephrosis. The tumour could not be completely removed, as it passed too deeply down. The next morning collapse took place, with loss of consciousness, rigidity of pupils, convulsions both of the trunk and extremities, and later on Cheyne-Stokes' respiration. As uremia was suspected, the right, kinked, ureter was drained. The breathing became quieter and the convulsions ceased. The following morning, however, the patient died, in spite of saline infusions and excitants. The autopsy quite cleared up whatever was doubtful. There was a tumour (sarcoma) the size of a hen's egg of the posterior lobe of the brain, numerous metastases the size of walnuts in both lungs, a metastatic tumour of the glands extensively adherent to the vena cava, and to some extent penetrating it.

It was remarkable that all these growths had so little affected the vital organs that the soldier was on duty up to a few days before his death. All that had been observed was that for a few weeks he had been morose and negligent, there had been twitching of the left eye, and he had once complained of weakness of sight. The cause of death was the cerebral hæmorrhage, of which the first symptom was the vomiting that took place the day after the operation.

AUSTRIA.

Vienna, Nov. 10th, 1907.

Radiation and Necrosis.

At the Gesellschaft, Churmont exhibited a case on which he had repeatedly operated for empyema in the frontal bone from excessive use of the Röntgen rays. By separating a portion of bone and periosteum from the margin of the wound, he succeeded in closing the wound completely.

Schopf recorded a similar case of an osseous defect in the left frontal bone involving the orbital margin and ethmoid bones. He used Fraenkel's celluloid heteroplastic appliance, and obtained an excellent result, both cosmetically and functionally.

Hypertrichosis.

Halban showed a gravid guinea-pig with an enormous profusion of hair on the body which always occurred in pregnancy. He has devoted two years to this subject in the lying-in hospital, and finds this is the case in the skin of females of the human sex also.

Detachment of the Retina.

Sachs described what he termed a new method of treating detached retinas, and exhibited a woman, æt. 49, on whom he had performed the operation for blindness of the right eye owing to the retina being completely separated from the sclerotic base. Later the left eye commenced in the upper quadrant, which he treated by puncture, injections of a salt solution, and a bandage.

His new operation for the right eye was described as first anæsthetising by means of cocain, separating the superior rectus muscle, then with a curved knife cutting the ball equatorially parallel to the ora serrata, and liberating the serous fluid from below the retina. The result was a replacement of the retina, and a rapid healing of the linear incision, as the precaution of cutting the rectus muscle hastens the repair. In this case a small amount of fluid collected afterwards behind the retina between the cicatrix of the incision and the ora serrata, but this did not interfere with the field of vision. He thought this opening produced a mole or dam to the extension backwards of the fluid. He had operated on several cases with perfect success, and thought he saw in this operation as great a future as that of aspirating the thorax for pleuritic effusion.

Müller thought that great caution was necessary where ablatio retinæ existed, as other operators in different countries had not obtained such favourable results—indeed, they condemn the operation as absolutely injurious. Every form of puncture was deleterious and damaging to the eye, more particularly in those advancing in life.

Secondary Vaccination.

Mautner showed a child from Prof. Monti's Klinik, æt. 5, with secondary vaccination on the right side of the tongue. The child was vaccinated on the right arm previously, which took very well, but after the vesicles of the arm broke it became very itchy, which caused the child to rub them with its fingers, which it subsequently put in its mouth, with the result that a large vesicle formed on the right side of the tongue. The child appears to have had a carious tooth that cut the tongue in the first place, admitting the virus to the system, and producing the usual primary vesicle. Now arises the question—would the child have taken small-pox as easily as if it had never been done in the first instance? It seems all the susceptible matter was not used up, or the second vaccination should not have been successful. This subject is still far from satisfactory.

Necrosis of Bone.

Eiselsberg showed a patient on whom he had operated for necrosis in the upper arm. The entire humerus was removed, but the periosteum preserved, from which restitution was expected. The function of the arm was now good, while the muscles were strong, and the grip of the hand as firm as ever. The Röntgen rays revealed a small lamella of bone at the distal end of the humerus, and a small spicula about the middle of the upper arm. The upper arm can be twisted round 360 degrees, entirely checking the pulse at the radial artery.

A Giant Growth.

Kienböck, amid some amusement, brought in an Anak, æt. 27, in excellent health. He was 202 centimetres, = 6 ft. 8 in. in height, and weighed 90 kilos., or 15½ st. The hands and feet were proportionately long, 24 and 32 centimetres respectively. The cranium was not increased in proportion to the body, being 56.5 centimetres in circumference; forehead low and face long; heart orthoscopic on the Röntgen shadow, and measuring 13 centimetres horizontally.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Clinical Teaching in Glasgow.—A discussion on this subject has been going on in the columns of the daily Press for some weeks, the question at issue being whether the Western Infirmary is able to give adequate instruction, or whether the other Glasgow hospitals should take part in clinical teaching. Though there is no compulsion on the students to attend the Western Infirmary, its proximity to the University and the fact that the Clinical Professors, who are the examiners, teach there, offer a strong inducement to the students, with the result that some of the clinics are overcrowded. It is suggested by way of remedy that all the Glasgow clinical teachers should be made examiners, whether they are attached to the Western Infirmary or not, and that cars should be run at special hours, so as to get over the difficulties of distance. The supporters of the *status quo* urge that what is required is a more uniform distribution of the students among the clinics of the Western Infirmary. On the medical side of the hospital the students are fairly well divided among the examining and the non-examining physicians, but on the surgical side two-thirds of the students crowd to one teacher of clinical surgery, while the remaining five teachers, though one is an examiner, have only one-third of the students. Evidently, therefore, it is very desirable that some means of dividing the students among the six surgeons should be devised; were this done, it would be easy to limit the clinics to about 25 men, and to arrange that each student should attend the wards of several teachers in succession.

Edinburgh University: Lord Rector's Assessor.—The Rt. Hon. R. B. Haldane has appointed Mr. James Walker, C.A., his assessor on the University Court in succession to Lord Dundas. No better representative of the interests of the students could have been selected than Mr. Walker, who for years as treasurer of the union has laboured indefatigably on their behalf. His appointment will be deservedly popular.

Glasgow Graduation Ceremonial.—The disorderly scenes which were witnessed at the recent graduation ceremonial were discussed at a mass meeting of the students held on the 11th inst. A resolution was passed expressing regret at the disorder, particularly as it had been construed as showing a lack of sympathy with the Principal, and apologising for the same. Mr. Watson, President of the S.R.C., said he confessed they had unwittingly insulted the Principal—at least he regarded their conduct in that light. In view of this, the only manly course was to offer an apology to Principal MacAlister. The apology was to the Principal personally, not to the Senatus. Two students were appointed to wait on the Principal, and convey the apology to him in person. The cause of the disturbance is alleged to be the insufficient accommodation provided in the Bute Hall. It had been desired to secure the St. Andrew's Hall for the graduation, but the proposal was overruled by the Senatus—hence the rowdyism.

BELFAST.

The Irish University Question.—The questions connected with Irish University education, and specially the question of the desirability or otherwise of having a Northern University in Belfast, are a good deal before the public now, partly on account of Mr. Birrell's recent speech, and partly on account of the plain words of Lord Kelvin in his address read at the opening of the new laboratories at Queen's College a few weeks ago. During the past week there have been two public references to the question in Belfast. On Monday night Professor Moore, of Liverpool, gave an address to the Medical Students' Association at Queen's College, in which he dealt with University education generally, and referred specially to local conditions in Ulster. He expressed in the strongest possible terms his belief in the desirability of an Ulster University and his confidence in its success. On Friday, at the distribution of prizes by Lord Shaftesbury, the Lord Mayor, to the boys of the Royal Belfast Academical Institution, one of the speakers, Mr. R. T. Martin, a solicitor closely connected with College affairs, spoke in much the same sense. There can be no doubt that the public generally is being educated up to the idea of a local University, and a project which a few years ago was openly derided and scoffed at by most University men, and all non-University men, is now seriously discussed on all sides, and received with a large amount of favour.

The Milk Supply.—Mr. Nathan Strauss, of Heidelberg, has offered to the Belfast Corporation a complete outfit for the Pasteurisation of milk, but the offer had to be refused, as the necessary expenditure for the working of the scheme would not be legal, and would certainly be surcharged by the Local Government Board auditors. Mr. Alec Wilson, whose model dairy at Belvoir Park was inspected by Lord and Lady Aberdeen during their recent visit to Belfast, has written an interesting letter to the local Press on the question of tuberculosis and milk. He says that experience shows clearly that a slight increase in price will pay the dairyman well for his trouble in cleaning up and supplying milk for which he can produce medical and veterinary certificates; but to sell milk warranted free from tubercle is a much more serious affair. If one is content with a certificate that there are no clinical signs of tubercle, and that the udders of the cows are free from disease, the milk may be sold at fourpence a quart from the dairy worked on modern hygienic lines. But to warrant the milk free from tubercle means the systematic testing of the cows with tuberculin, and the slaughter of some 30 per cent. of those tested, as well as many precautions to avoid infection by other tuberculous animals, such as pigs. This in practice will add about 25 per cent. to the price of the milk, and it remains to be seen whether there is a demand for such milk. If there is, it will soon be supplied.

LETTERS TO THE EDITOR.

DISEASES OF TWINS.

To the Editor of The Medical Press and Circular.

Sir,—Will you kindly permit me to make use of the columns of your medical journal under the following circumstances?

On re-reading Francis Galton's "History of Twins," published in his work, "Inquiries into Human Faculty," it occurred to me that, as he has proved the greater strength of Nature over Nurture in this investigation, the same material slightly modified would be able to conclusively establish the relative importance of the factors of individual constitution and specific invading organisms in the production of disease.

Accordingly, I had, as a beginning, 200 circulars and addressed return envelopes printed, and subsequently dispatched a little over 50 of them to test the kind of response I was likely to meet with. I had replies from over 40 per cent., and although I took the precaution of sending only to general practitioners of more than ten years' standing, the evidence obtained was decidedly disappointing. I had imagined, as twin births are said to occur once in about every 90 maternity cases, that most practitioners who had been in practice for a few years would have had some experience on this subject, even allowing for the fact that twin children frequently die.

To my surprise, no less than 45 per cent. of my replies stated that no experience had so far been obtained; 8 to 10 per cent. apparently do not practice midwifery, or discourage it, and have not attended twins at any later age period; and only 45 per cent. have had any experience, however meagre. Of these, most appear to have had a few maternity cases, though the answers were not always clear on this point: in addition, 25 per cent. have once attended twin children and 30 per cent. once adults. I am not quite certain whether one of these latter did not attend adult twins twice.

The number of replies is, of course, far too small to make any generalisation upon the matter. A practitioner may possibly be unaware that he is treating a twin when the pair are separated. Still, allowing for this, the scarcity of material is remarkable. The explanation may be possibly due to an error in assuming that hospital statistics, drawn from the poorest citizens, apply equally to all classes. In any case, it is evident that I must appeal to a much larger circle of medical men than can be done by any method of private correspondence, in order to obtain the necessary information.

Would any of your readers, therefore, who have in their possession evidence on the points mentioned below, kindly communicate with the writer whose address is appended?

Twins, if they are true twins, are usually of the same sex, and are most frequently either much alike or much unlike.

(1) Of like twins of the same sex at any age period, have you any medical experience of their suffering simultaneously or independently from like or unlike diseases in like or unlike (separate) surroundings?

(2) Of unlike twins of the same sex at any age period, have you any medical experience of their suffering simultaneously or independently from like or unlike diseases in like or unlike (separate) surroundings?

Please name specifically all diseases referred to, as this point is very important.

Any additional information on the subject would be welcomed, and all remarks will, of course, be treated confidentially.

I would be greatly obliged if Continental journals would insert this letter in their issues.

Thanking you and your readers in anticipation for your kindness in considering my letter,

I am, Sir, yours faithfully,
J. Lionel Tayler, L.R.C.P., M.R.C.S.
8, Adys Lawn, Willesden Green, London, N.W.

ANTI-TUBERCULOSIS DISPENSARIES.

To the Editor of The Medical Press and Circular.

Sir,—In your leading article of yesterday on the Medical Officer's report to the Local Government Board, you lay due emphasis on the significance of anti-tuberculosis dispensaries. The article suggests, however, that these are extra-British in conception and development. You suggest that they constitute a French experiment, worthy to be carefully watched with a view to possible imitation. I would remind you, however, that both the conception and evolution of the anti-tuberculosis dispensary are essentially British.

In the campaign against tuberculosis, which was initiated in Edinburgh in 1887, "the first step" (I am quoting from the official report) "was the establishment of the consumption dispensary. The purpose of the dispensary was the formation of a central institution, to which persons of the poorer classes, affected by tuberculosis, might be invited and directed. The idea was a novel one twenty years ago. For more than a decade the Victoria Dispensary for consumption was alone of its kind. Familiarity with its object has led more recently to widespread recognition of the significance of the Dispensary. During the past half-dozen years, consumption dispensaries have been created in Belgium, France, and Germany, and in the last year or two similar dispensaries have been founded in America, the United Kingdom, and the Colonies. It is matter for congratulation that the conception has proved to be of such universal application and value."

In the important Memorandum on the Administrative Control of Pulmonary Phthisis, issued by the Local Government Board for Scotland on March 10th, 1906, the significance of dispensaries for pulmonary phthisis is thoroughly recognised. "In towns and other thickly populated localities, where the number of phthisical patients is large, the local authorities will find it advisable to institute a dispensary or dispensaries. In Edinburgh, the Royal Victoria Dispensary for Tuberculosis, organised by Dr. R. W. Philip, has worked successfully for 18 years, and the suggestions here made are largely based on the experience of that Dispensary."

At the inauguration of the new buildings in connection with the Royal Victoria Hospital for Consumption on October 25th last, Dr. Leslie Mackenzie, speaking on behalf of the Local Government Board for Scotland, said:—"We adopted his scheme as a national system for the administration of the campaign against tuberculosis in Scotland. The Dispensary in Dr. Philip's scheme is the centre, the exchange, the information bureau, the nucleus of the whole system. In the Victoria Dispensary we have a type of what we hope to see realised in the district of every local authority in Scotland. The function of a Dispensary is to act as an information bureau, a supervision bureau, a centre of treatment for such patients as do not need hospital treatment, but who can benefit by supervision at their own homes."

These quotations will, I think, suffice to show that the Consumption Dispensary is no longer at the experimental stage, nor does it seem necessary for us to go outside our own country for a working model.

I am, Sir, yours truly,
Alexander Christison, Bart., M.D.

Edinburgh, November 15th, 1907.

HOT-WATER OPERATING TABLES.

To the Editor of The Medical Press and Circular.

Sir,—As I can claim priority for suggestion of hot-water operating tables as a preventive of shock during, or subsequent to, sustained operations (abdominal or otherwise), I should feel much obliged if any members of the surgical staff of hospitals would kindly state their opinion of such a form of table. My suggestion (which was adopted by most surgical instrument-makers, and who still stock the said table) appeared so long ago as 1889 in The Medical Press and Circular and the other medical papers, so there has been ample time to judge of the practical value of my suggestion, and I should much value the opinion of those who have found it has contributed to the prevention of shock and the assistance to recovery after operation.

Yours very truly,
Alexander Duke, M.D.

London, W.

A ROYAL COMMISSION ON QUACKERY.

To the Editor of The Medical Press and Circular.

Sir,—One of your medical contemporaries has sought to throw some cold water on the project of a Royal Commission on illicit practice, by the statement that medicine is not an exact science, and that quacks would produce patients who had been cured under their treatment, and thus would scatter dust in the eyes of the Commissioners. Does the State ask whether political economy and the operations of the money market are exact sciences before devising laws to protect the people against common swindlers, burglars, and pick-pockets? The State acknowledges that its duty is to protect the people, and especially the weak and simple, against the wiles or the violence of the predatory classes. If the arts of medicine and surgery together could not claim a single scientific fact upon which to base themselves, it would be still easy to demonstrate to all sensible men the fact that fraudulent quackery is founded solely upon falsehood—a mass of lies gross as a mountain, open, palpable. Many cases within late years in the civil and criminal courts have shown that the production of many patients "cured" by quackery is not enough to prevent the ruin of a quack even when defended by leading counsel. The average juryman is quite able to recognise that the quack's claim as a healer really amounts to a claim to be a miracle worker; and the juryman can see that miracles cannot be wrought in the removal of organic disease by the inert messes in way of drugs, or the bogus apparatus, which form the stock-in-trade of the quack. In civil cases where the exposer of quackery is on his defence—and even the difficulties which civil procedure gives rise to are great—the quack always comes out a sorry figure; how much more certainly would he fare badly before a tribunal like a Commission, which, although it might include some weak or prejudiced members, would be composed in the main of sober-headed men of judgment. The result of the Australian one-man Commission, has, it seems to me, demonstrated the practicability and the hopefulness of a Commission (which would be armed with much wider powers at home); and I sincerely trust that you will continue to exert your influence in support of the movement first suggested in your paper.

Yours, etc.,
Reformer.

November 15th, 1907.

[We should welcome the outspoken views of readers on this most important and practical of professional topics.—Ed., M. P. & C.]

OBITUARY.

SIR CHARLES F. HUTCHINSON, J.P., M.D.Ed., M.R.C.S.

It is with great regret that we record the death of Sir Charles Hutchinson, which took place last week. It was known that Sir Charles had been desperately ill for some time, but the accounts had been more satisfactory of late, and his friends hoped he had weathered the storm. Sir Charles Hutchinson was educated at Edinburgh University, where he graduated M.B. and C.M. in 1872, and M.D. in 1874. After some preliminary steps, he settled down in practice in the Riviera, where he attained great popularity, and had a large clientèle for many years. He gave up practice to stand for Parliament, and he will always be remembered in political circles as the "Victor of Rye." His sensational victory in that constituency was the harbinger of the many late Liberal victories at the polls. Unfortunately he lost his seat at the General Election, though he was wont to say he helped sixty other candidates to win theirs. All who knew Sir Charles Hutchinson, whether they were on his side of politics or not, were his admirers. His genial presence, his warm heart, his witty speeches, and his racy manner won all hearts. His defeat at the General Election pained him greatly, as in Parliament he was in an atmosphere that just suited him. The Government, by way of consolation, gave him a knighthood, and we are sure it was as popular an honour as any in the list.

FLEET-SURGEON FREDERICK HARVEY, M.R.C.S.

We regret to record the loss of Fleet-Surgeon Frederick Harvey, whose death took place on November 12th, in his 89th year. He entered the Navy as an assistant surgeon two years after Queen Victoria ascended the Throne. The first vessel to which he was appointed was the "Beacon," employed on surveying duty in the Mediterranean. He was employed on similar duty in the following year, and during the winter of 1842-43 was in medical charge of the officers and men appointed to search for sculptured tombs and marble antiquities in Xanthus. In 1849 he was promoted to the rank of surgeon, and joined the "Sphinx," Captain C. F. A. Shadwell, in the East Indies. When trouble arose with Burmah in 1852, in this vessel he took part in the various operations, and received the medal and clasp. He was promoted to Fleet-Surgeon in 1861, and retired from the active list in 1874. He was awarded a Greenwich Hospital pension in 1894.

A. MacTIER PIRRIE.

We regret to announce the death, at the early age of twenty-eight, of Dr. A. MacTier Pirrie, who, after gaining high honours, including the Carnegie Research Fellowship, in anthropology, was appointed anthropologist to the Wellcome Research Laboratories at the Gordon Memorial College, Khartoum, and went out to the Soudan in the autumn of 1906. Under the direction of Dr. Andrew Balfour, the director of the laboratories, Dr. Pirrie made his first expedition up the Nile to the southern limits of the Soudan, and penetrated to remote parts of the Bahr-el-Ghazal. A second expedition took him to the borders of Abyssinia.

On the latter occasion he contracted fever, and was compelled to return to England. He presented a paper on his expeditions at the last meeting of the British Association, but was prevented from being present on account of his illness. Dr. Pirrie brought back a valuable collection of objects of anthropological and other scientific interest, and at intervals during his illness he was engaged on his report to the Carnegie Institute and the Wellcome Research Laboratories, Khartoum, for which institutions he acted jointly in the work he carried out in the Soudan.

JOHN GARNER, M.A., DUB., L.R.C.S. AND P., ED.

Dr. John Garner, Inspector-in-Chief of the Egyptian Public Health Department, died at Cairo on October 26th after a short illness. He was third son of Dr. W. Hastings Garner, for over 30 years Resident Medical Superintendent of Clonmel Asylum. He was a graduate in arts of Trinity College, Dublin, and L.R.C.P.S., Edinburgh. He began his professional career as assistant surgeon of the Co. Down Infirmary, and, after some subsequent service, went out with the Austin expedition for the delimitation of the Abyssinian frontier in the capacity of surgeon in charge. On his return from this expedition he obtained a post in the Egyptian service, in which he worked until his death. In 1905 he married Miss Hastings, of Downpatrick, and so leaves a young widow to mourn his early death.

ROBERT FITZROY BENHAM, M.R.C.S.

We regret to announce the death of Mr. Robert Fitzroy Benham, of Earl's Court Square, a well-known surgeon, who founded the Queen's Jubilee Hospital, Richmond Road, Earl's Court, which has since been re-named the Kensington General Hospital. Mr. Benham, who was fifty-four years of age, was the inventor of numerous surgical and other appliances. He was educated medically at St. George's College, and took the diploma of M.R.C.S.England.

LITERARY NOTES.

We are at a loss to conceive what motive could have prompted Dr. Herbert Hart to publish "Some Successful Prescriptions," written, we are informed, "on Monday, August 12th, 1907, after the evening surgery." Under the head of "Skin Diseases," without any further explanation, we are recommended to give 15-grain doses of salicin. This, the author states, splits up into carbolic acid and salicylic acid, which, when absorbed, "meet and destroy the pathogenic microbe," apparently whether present or otherwise. All the 17 or 18 prescriptions are stock formulæ, without the slightest claim to originality.

⁂

The second edition of a book on "The Hair and Its Diseases" has just been published by Messrs. Baillière, Tindall and Cox. Its author, Dr. David Walsh, has devoted a good deal of special study to this strangely neglected subject. His advice to general practitioners to acquire the elements of the subject is sound enough, for they would be thereby enabled in many instances to keep their patients from drifting into the hands of quacks. This little handbook is short and concise, but covers all the ground likely to be broken in ordinary practice. From a casual inspection it appears to register a considerable advance on the first edition, and to be well worthy of the general practitioner's attention.

⁂

It would be difficult to over-estimate the value of the "Index-Catalogue" of the library of the Surgeon-General's Office, United States Army, Vol. XII., Second Series, which has just reached us. Especially interesting must it be to those engaged in literary work, as it renders available the literature of modern medicine and enables the student to trace the evolution of scientific medicine. From the report of Surgeon McCaw, the librarian, we learn that the present volume contains 5,476 author-titles, 10,996 subject-titles, and 35,324 titles of articles in periodicals. So far as published, this great Index-Catalogue contains 290,862 author-titles, 367,104 book-titles, and 882,301 titles of articles in periodicals. But the mere enumeration of figures gives a very inadequate idea of the value of the work and of the obligation of the medical profession to the United States Government for their enlightened liberality in preparing and providing for the benefit of students such a stupendous, accurate, and practically useful publication, which in no niggardly spirit they bestow on the medical libraries of the world.

⁂

Messrs. Baillière, Tindall and Cox are announcing a particularly attractive and valuable set of new medical works. First of all we notice "Axenfeld's Bacteriology of the Eye," a standard book which has been translated by Dr. Angus Macnab. Then we have an important work on "Tropical Medicine," by Castellani and Chalmers, two authorities who have studied their subject first hand in hot climates. Freyer is represented by a volume on "The Surgery of the Urinary Organs." Major Herbert has a monograph on "Cataract Extraction," founded on extensive work in India. Kelynack contributes a volume on "Tuberculosis in Infancy and Childhood," a subject on which he is entitled to speak with authority. A practical book on "Operative Midwifery" has been written by Professor Kerr, of Glasgow; and "A Manual of Pathology," by Professor R. T. C. Leith, of Birmingham, is in the press, and a much-needed handbook on "Meat Inspection" is contributed by Dr. W. Robertson, Medical Officer of Health, Leith. Swan is the author of a note-book in the "Aids" series on "Genito-Urinary Diseases," and Turner publishes a "Pocket Osteology." Baker has a work on "The Spectroscope," and Gardner one on "Anæsthesia for Surgical and Dental Operations." This is a remarkably good record of new productions for a single firm.

REVIEWS OF BOOKS.

SURGICAL APPLIED ANATOMY (a).

This deservedly popular handbook is a marvel of compactness, and in its present form leaves little to be desired. Forty-three specially prepared figures have been added, and many of the others have been redrawn, while colours have been freely used to make the illustrations more effective. Surgical anatomy is not subject to fashion, and is less amenable to progress than certain other sciences germane to medicine; but wherever current views have been modified in deference to greater knowledge, the change has been duly embodied in the text. Well printed, and neatly and solidly bound, this little volume will certainly consolidate its hold on students of medicine.

NERVE DISEASES (b).

This is a very handy little guide to the study of disease of the nervous system, especially intended for the general student, only the commoner conditions, such as every medical student may expect to meet with, coming under consideration. After describing the essential features of the anatomy of the nervous system, which is, of course, an indispensable step to the comprehension of the pathological conditions, the author leads up to the methods of investigation, first general, then particular. In reading this little volume, we have been struck by the concision and lucidity of the author's literary style, and we do not remember ever having seen these morbid states and their phenomena described with such sobriety and plainness. It is to be feared that students are not infrequently discouraged by the extraordinary terminology and complexity that have seemed to be inseparable from this subject, but we recommend any such to invest in Dr. Clutterbuck's unpretentious little manual, which will assuredly give them a working familiarity with all diseases of the nervous system likely to require diagnosis at their hands.

(a) "Surgical Applied Anatomy." By Sir Frederick Treves, Bart., G.C.V.O., C.B., F.R.C.S.; Sergeant Surgeon-in-Ordinary to H.M. the King, Consulting Surgeon to the London Hospital, etc. Fifth Edition. Revised by Arthur Keith, M.D., F.R.C.S. Cassell and Co., Ltd. 1907.

(b) "Nerve Diseases." By L. A. Clutterbuck, M.D., B.S. (Durham); Hon. Physician St. Marylebone General Dispensary, etc. London: Scientific Press. 1907. Price 3s. net.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Vaginal Ovariotomy During Pregnancy.—Democh (*Monatsschrift für Geb. und Gyn.*, Bd. XXVI., Hft. 2) begins a paper on this subject with a review of the cases of ovariotomy per vaginam during pregnancy and during parturition which have already been recorded. He then describes a new case. The patient was a IV.-para in the second month of her pregnancy. A cyst the size of a child's head, and very adherent, lay behind the pregnant uterus, and being thus a grave danger during labour, it was removed by posterior colpotomy. The pregnancy was uninterrupted. The author concludes that in general the vaginal route is to be preferred for ovariotomy during pregnancy.
G.

Appendicitis During Pregnancy and During the Puerperium.—Stähler (*Monatssch. für Geb. und Gyn.*, Bd. XXVI., Hft. 2), having first described a case of appendicitis during pregnancy which he had observed, and having mentioned similar cases from the literature, comes to the following conclusions. Appendicitis, especially the severe forms, is rare during pregnancy and the puerperium. The causes of the origin of appendicitis during pregnancy are not different from the causes of origin during the non-gravid state. A greater liability to recurrence during pregnancy does not exist; at most as a result of the exertions of the uterus during labour old foci may be temporarily re-awakened. The author then describes the symptoms, the diagnosis, and the differential diagnosis of appendicitis during pregnancy. As regards the treatment, he advises early operation in acute as well as in acute recurring appendicitis in pregnancy. The proposal of some authors that the appendicectomy should be followed by immediate emptying of the uterus is in the author's opinion quite wrong. Drainage of the abscess cavity through the posterior fornix of the vagina, if such should be necessary, is not very dangerous, even though labour should come on, as a consequent infection of the uterine cavity has not been observed in any of these cases in which it has been performed.
G.

Hebosteotomy and its Position in Practical Obstetrics.—Leopold, at the 79th congress of the Deutscher Naturforscher und Aerzte (*Zentralblatt für Gynäk.*, Nr. 43, 1907), described his technique as follows:—With the patient under an anæsthetic and with the help of an assistant, a small stab is made through the skin down on to the pubic tubercle either on the left or on the right side of the symphysis. Through this Döderlein's needle is inserted and pushed from above downwards behind the os pubis under the control of the index finger in the vagina, so that the point of the needle appears between the smaller and the greater labia about a finger's breadth away from the angle of the pubic arch. The saw is now fitted to it, and when it has been drawn backwards the bone is sawn through. From his experience of over sixty cases Leopold comes to the following conclusions. The hebosteotomy is of most value when the conjugata vera varies from 6½ to 8 cm. The subcutaneous insertion of Döderlein's needle is best performed from above downwards. When there has been sufficient practice and experience of the operator injuries to the bladder are scarcely possible. After the hebosteotomy, which is only performed when the cervix is fully dilated, the uterus should be immediately emptied by either the forceps or version, according to the presentation of the child. Lacerations of the vagina must be carefully sutured. If the urine should be bloody a catheter must be kept in the bladder for several days. Leopold considers gonorrhœa to be a contra-indication to the performance of hebosteotomy, and advises instead the Porro operation, the extraperitoneal Cæsarean section, or even the perforation of the living child. Leopold considers that only an obstetrician who fully understands the operation and all its possible complications should undertake it, otherwise, when it is impossible to send the patient to a hospital, it would be better to perforate the child.
G.

The Relationship between Diseases of Women and Disease of the Intestine was discussed by Mueller (München) at the same congress (*Zentralbl. für Gynäk.*, Nr. 43, 1907). As a result of the inflammations of the intestinal mucous membrane, both mechanical and chemical, and of that produced by constipation, the development of intestinal polypi, intestinal ulcers, hæmorrhoids, periproctitis and periproctitic exudates and abscesses, parametritis, endometritis, ante-flexion and retroposition, retroversio and flexio uteri, parametritis and perimetritis atrophicans retrahens, pelvic peritonitis, perimetritis, and salpingo-oöphoritis is brought about. Through stenosis of the rectum, which is a result of posterior parametritis, catarrh of the large intestine, intestinal atony, sigmoiditis, left-sided oöphoritis and cystitis are produced. From the vermiform appendix arises salpingo-oöphoritis dextra, more rarely sinistra, pelvic peritonitis, etc. From the intoxication which is produced, chlorosis, rheumatism, gout, neurasthenia may result, or if already present, are aggravated. The treatment consists in warm applications and massage. It is important to obtain soft motions and through antiseptics, etc., to bring about healing of the diseased intestine. The author considers that it is wrong to believe that 90 per cent. of inflammatory diseases in the female are due to gonorrhœa; in his opinion 90 per cent. are due to the intestine.
G.

Thrombosis and Embolism after Gynæcological Operations.—Zurhelle read a paper on this subject at the same congress (*Zentralbl. für Gynäk.*, Nr. 43, 1907). Post-operative thrombosis is most frequently seen after myoma operations. The author saw it in 2.75 per cent. of all the myoma operations in the Frauenklinik Bonn. The cause is probably the chronic anæmia, the ergot treatment, and the other disadvantages of the palliative treatment when the heart has already been injured by the presence of the myomata. Next in frequency as a cause of post-operative thrombosis come the malignant tumours, when cachexia, ascites, etc., are present, marantic thromboses can be easily explained. For other gynæcological diseases, for example, tumours of the adnexa and displacements of the uterus, there are no special causes for thrombosis to be observed, but more general causes, for example, infection, cardiac changes, and anæmia. Other causes for this complication are the cooling of the abdominal cavity during laparotomy, injuries to the blood vessels, injury to the heart by the narcosis, obstruction to the circulation of the blood in the legs through tight compresses, meteorism, prolonged rest on the back, etc. The thrombosis is as a rule not due to one cause, but to quite a number of causes of which many work together. Better class patients are more liable to post-operative thrombosis than women of the working class. This is probably due to want of exercise, feeble circulation, want of muscle nutrition, and especially of the heart. There are three forms of thrombosis after gynæcological operations which are to be differentiated from one another:—(1) Thrombosis of the pelvic veins. The diagnosis is very difficult, and the condition very often produces pulmonary embolism, probably because the pelvic veins are without valves. (2) Thrombosis of the femoral vein, the most frequent form of post-operative thrombosis. It also leads to pulmonary embolism. It usually commences just underneath Poupart's ligament, or in the popliteal vein. It is generally a form of marantic thrombosis, and in the majority of cases is produced mechanically in cases of weak cardiac action. (3) Thrombosis of the saphenous vein, with reddening of the skin. On palpation this feels like hard cords and knots. This form does not produce pulmonary embolism. The author has never been able to prove from any of his cases the correctness of Mahler's observation that in a typical thrombosis chart a gradual rise of the pulse rate is to be found with a normal temperature. G.

Treatment of Peritoneal Wounds.—As the result of examination of a large series of cases, Pankow (*Monatssch. für Geb. und Gyn.*, Bd. XXVI., Hft. 2) concludes that cauterisation of the parietal or visceral peritoneum is followed by easy recovery of the peritoneal wounds as long as there is no hæmorrhage in the abdominal cavity, and that the formation of adhesions only occurs in exceptional cases. Wounds of the parietal peritoneum so severe as to produce diffuse points of hæmorrhage lead fairly often to adhesion formation. Healthy peritoneum affords the animal a greater protection against infection than that which has been injured and then treated with the thermocautery and absolute alcohol. The most unfavourable results are obtained when infection occurs in peritoneum which has been injured and not treated. In such cases adhesions are practically always formed. Consequently, during operation, all hæmorrhage should be controlled as far as possible, whether with the thermocautery or with absolute alcohol, in order that the danger of infection and of adhesion formation may be diminished. G.

The Scope of Treatment of Acute Pelvic Infections in Women by the General Physician.—Wesley Bovee (*Amer. Jour. Obst.*, October, 1907).—The writer's suggestions are, first, that the treatment of acute pelvic infections is, as a rule, not operative, but one of palliation and expectancy; second, that, practically, analgesics, other than the external application of ice, are not needed, and are harmful; third, that if surgical intervention becomes necessary during such acute stage of pelvic infection, it will be a simple procedure of vaginal incision and drainage, though extremely rarely will abdominal incision for this purpose be required; fourth, that a certain percentage of such infections result in symptomatic relief or cure by such palliative treatment. A very much larger proportion (the suppurative cases) will require operation, of which the vaginal incision and drainage, whether during the acute stage or later, will be sufficient, and when it fails radical surgery will have to be employed; and, fifth, that very rarely indeed will radical abdominal operation be required during the acute stage of pelvic infection. F.

Toxæmia of Pregnancy Relieved by the Administration of Thyroid Extract.—Fry (*Amer. Jour. Obst.*, October, 1907).—The patient suffered from headache, insomnia, and indigestion; the specific gravity of the urine had fallen to .1005, and the urea was less than one-half of 1 per cent. No albumen or casts were present. No change whatever was made in the diet or mode of living, but 5 grs. of thyroid were given t.i.d. The examination of urine made 36 hours after treatment was begun showed a rise of specific gravity .1018 and percentage of urea to 2.5. The above symptoms disappeared, and the tablets were then administered twice daily for some weeks. F.

Prolapsus Funis: A New Method of Treatment in Cephalic Presentations.—Stowe (*Surg. Gyn. and Obst.*) describes his new method, in which his idea is to try to restore the normal conditions of the first stage of labour by introducing into the uterine cavity normal saline solution to take the place of the liquor amnii and to provide a substitute for the membranes. Through a Voorhees bag, from base to apex, he has a separate rubber tube fixed without any connection with the interior of the bag, and when the bag is in position in the cervix, sterile salt solution is slowly injected into the uterine cavity. About one pint is generally sufficient. The cord is, of course, replaced before the bag is introduced and filled. The bags are made in two sizes. If there is very little dilatation of the os, the smaller one is used, to be replaced later on by the large one. When the larger one is expelled, the os is fully dilated, and immediate delivery by version can be done. If too much fluid is injected into the uterus, the pains will become very severe. Some of the fluid should then be allowed to escape. If there is much leakage by the side of the bag, fluid should be injected from time to time. F.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England.

An ordinary meeting of the Council of the Royal College of Surgeons was held last Thursday, Mr. Henry Morris, F.R.C.S., President, in the chair. Eighty-seven candidates who had passed the required examinations and conformed to the bye-laws were admitted Members of the College (a complete list will be found under the heading, "Pass Lists"). No fewer than forty-two of these candidates were University students.

A letter from the deans of the medical faculties of the Universities of Leeds, Liverpool, and Sheffield suggesting the desirability of altering the times of year at which the primary examination for the fellowship of the college are held was read and referred to a committee for consideration.

The President reported that the Bradshaw Lecture would be delivered by Mr. Rickman J. Godlee, Vice-President of the College, on December 6th, at 5 p.m., and that the subject of the lecture would be "The Prognosis and Treatment of Tubercular Disease of the Genito-urinary Organs."

A report was received from the Museum Committee with reference to the appointment of a Conservator of the Museum. It was determined that the recommendations of the Committee should be further considered at the next meeting of the Council, on December 12th, and that the vacant appointment should be advertised after that date.

A letter was read from Dr. Liveing reporting that the appointment of Mr. Edmund Owen, F.R.C.S., as Visitor to the Egyptian School of Medicine for the examinations to be held at Cairo in December next had been confirmed by the Royal College of Physicians. It was determined to add Giggleswick School, Settle, Yorkshire, to the list of institutions recognised by the examining board in England for instruction in chemistry and physics, and Wyggeston School, Leicester, which is already recognised by the Board for instruction in chemistry and physics, was also recognised for instruction in biology.

THE DIRECT REPRESENTATION OF MEMBERS ON THE COUNCIL.

The Secretary announced the notices of motion for the annual meeting of Fellows and Members on Thursday, November 21st, at 3 p.m., to be as follows:—

To be moved by Mr. Frederick W. Collingwood: "That the President and Council of the Royal College of Surgeons be asked to use their moral influence with hospital authorities to recognise Members of the College (who are also in almost all cases Licentiates of the Royal College of Physicians) as having equal rights with provincial, Scotch, and Irish graduates to become candidates for hospital appointments."

To be moved by Mr. Joseph Smith: "That this twenty-third consecutive annual meeting of Fellows and Members again re-affirms the desirability of admitting Members to direct representation on the Council, which as now constituted does not represent the whole Corporation."

To be moved by Dr. W. G. Dickinson: "That this meeting regrets that the Council has omitted from their report any reference to the opinion of his Majesty's Government on the question of the representation of Members, and requests the President to supply the omission by communicating the same forthwith."

To be moved by Mr. George Brown: "That this meeting notes with satisfaction that the Council intends to take a poll of the Fellows and Members on the whole question of admitting women to the diplomas of the College, and this meeting further urges that a similar course be taken with regard to the proposal for direct representation of the Members upon the Council."

To be moved by Mr. H. Elliot-Blake (Bognor): (*a*) "That this meeting of Fellows and Members of the Royal College of Surgeons wishes the Council to report as to their willingness to join the Royal College of Surgeons and its work with the University of London (so as to form an Imperial University of London), and whether they will approach the Royal College of Physicians for a similar conjoint action." (*b*) "That this meeting requests the Council to add a hood to the gown already worn by Fellows and Members."

Royal College of Surgeons in Ireland.

NOTICE has been given of an alteration of some importance in the regulations respecting admission to the Fellowship. Hitherto candidates have been divided into two classes—those who are graduates or Licentiates in Surgery of over ten years' standing, and those who have held such diplomas or degrees for less than that period. In the case of the former no examination has been imposed in anatomy and physiology, as apart from surgery; the test which has been imposed in their case being known as Grade 2. After the date mentioned Grade 2 will cease to exist, and all candidates alike will have to pass under the scheme known as Grade 1. This entails examination in anatomy and physiology and histology and surgical pathology, as well as in systematic, clinical, and operative surgery. The alterations will take effect from January 1st, 1910.

The Cork Medical and Surgical Society.

THE annual dinner of this Society was held on November 9th in the Imperial Hotel, Cork. The President of the Society, Dr. Moore, occupied the chair. After dinner, the following toasts were proposed:—"The King"; "The Cork School of Medicine," proposed by the City High Sheriff, and responded to by Professor Corby and Professor Pearson; "Our Guests," proposed by Dr. Lee, replied to by Professor Molohan and Alderman Meade; "The City High Sheriff," proposed by Dr. Cotter. Professor Pearson also proposed the healths of the two newly-appointed professors at the Queen's College, Dr. Windle and Dr. Barry, and Dr. Barry, in the absence of Dr. Windle, replied. The last toast was that of the Honorary Secretary, Dr. Booth.

Irish University Education.

THE latest pronouncement on the subject of University Education in Ireland was made by the Chief Secretary for Ireland at the opening meeting of the Catholic University College Literary Society. In this connection Mr. Birrell, who was subjected to some cross-questioning, said: "All I will say is that I believe that that question can be, and ought to be, and, please God, will be, solved in the next session of Parliament. I know no cause to which I would more willingly devote my life, and I know no cause in which I would more willingly suffer political extinction, than the cause of securing for the Irish people that higher education which justice demands that they should have, which it is imperatively necessary that they should have if they are to discharge the important duties already imposed upon them, and the still more important duties which cannot long be withheld from them. This battle will be a hard fight. Opposition there will be, I doubt not, both in Ireland and in England, to any such measure as I hope to be able to propose. . . . It can only be done by general support, by sympathy, and by feeling. I, at all events, pledge myself to do the very best that mortal man can do in this next session of Parliament, and if I fail, why then, gentlemen, I can promise you this—that you will be troubled with me no more."

Mr. Birrell has not as yet divulged the nature of the solution which he intends to offer for this long-standing question, but many things point to a probability of a rearrangement of the Royal University, either with or without the establishment of local Universities in Belfast and Cork. Our Belfast correspondent, in the present issue of this journal, refers to the growth of a feeling in Belfast in favour of a separate University, but there is at the same time in that city a strong body of feeling which opposes what it believes would be a University under the control of Presbyterian clerics. Mr. Bryce was dogmatic, and he failed. Mr. Birrell is optimistic, and there are many who hope that he will succeed, if, and only if, his sole end is the improvement of higher education in Ireland.

Devon Medical Man's Divorce.

IN the Divorce Court, on November 13th, Dr. William Pitt Palmer, of Babbacombe, Devon, was awarded a decree nisi and £2,000 damages on the ground of his wife's misconduct with Major Charles Barchard. There was no defence.

Mr. Willock said the marriage took place at Torquay on June 5th, 1895, the petitioner residing at Torquay. One son was born, in April, 1896. The co-respondent described himself as a retired major of the West Yorks Regiment. The petitioner strongly objected to his wife associating with the co-respondent. Mrs. Palmer began to neglect her home, and was frequently excited through drink. She went away from home, and would not give any explanation as to where she had been. He found she spent Christmas Day, 1906, at the co-respondent's house.

Dr. Palmer subsequently received a letter from the co-respondent posted in Bristol, in which he threatened to take proceedings against Dr. Palmer for defamation of character in alleging that he and the respondent had stayed as man and wife at Charing Cross Hotel. A few days later came a telegram from Major Barchard. Upon receiving this message the petitioner and his brother went to Bristol, and found the respondent and co-respondent together. Afterwards the respondent and co-respondent went to another address in Bristol, staying together as man and wife, the co-respondent finally going away, leaving the respondent at the place. Dr. Palmer filed his petition, and the co-respondent, not having insulted him enough, sent him a postcard:—

"Am in receipt of citation for divorce *re* your wife and yourself. As I do not intend to take all the responsibility on my shoulders, I shall cite others. I shall also prefer charges of collusion, cruelty, and neglect."

The petitioner gave evidence of his wife's relations with Major Barchard.

The Judge, in summing up, said he could hardly remember a case where the conduct of the co-respondent had been so serious.

The jury awarded £2,000 damages, and his lordship granted the petitioner a decree nisi, with costs, and the custody of the child.

Limerick Union Medical Officership Election.

IT is stated that the authorities, acting on the representation of the Local Government Board, have ordered the prosecution of some 16 persons, who, as alleged, were concerned in the election of Resident Medical Officer of Limerick Workhouse several months since, and respecting which election a sworn inquiry was opened in the month of June, and continued on various dates. It is further stated that the charge will be one of conspiracy and corrupt practices, and that the summonses will be served in the course of a day or two.

Interesting Workmen's Compensation Case.

BEFORE Judge Willis, K.C., in the Southwark County Court, on November 4th, an action was brought by Frederick Reeves, a shield driver, against Messrs. Price and Reeves, contractors, to recover damages under the Workmen's Compensation Act.

Counsel for plaintiff said the latter in May last was working for the respondents in Rotherhithe Tunnel, when, in passing from one stage to another, he slipped from a plank and fell upon a man who was using a large spanner. Plaintiff's jaw struck the spanner, and he subsequently went to the London Hospital, where an operation was performed upon him, a portion of his jaw-bone being removed. On July 29th he returned to work and continued working until August 19th, when he was compelled to again go to the hospital, and had been unable to work since. Counsel added that cancer supervened, and the plaintiff had to have a portion of his tongue cut away. The respondents contended that the formation of cancer in no way resulted from the accident, but the plaintiff's case was that it was directly due to it.

Several doctors gave evidence for and against the plaintiff's contention that the blow caused the cancer.

His Honour came to the conclusion that the cancer did result from the blow, and he ordered the plaintiff to be paid £1 per week during the time he remained incapacitated.

Cape Doctors Censured.

A SPECIAL meeting of the Cape Colonial Medical Council was held recently, at which there were present:—Dr. C. F. K. Murray (President of the Council), Sir Edmond S. Stevenson, Dr. Darley Hartley, Dr. Wood, and Dr. Johnston, with Advocate J. T. Molteno, legal adviser to the Council. In the case of Dr. McMullen, who was charged with having prescribed opium for purposes other than *bonâ fide* medicinal purposes, and in which judgment on a former occasion had been reserved, it was notified that the Council had found Dr. McMullen guilty of "infamous and disgraceful conduct in a professional respect." A similar charge was preferred against Dr. Frederick R. Kruger of Cape Town, and he was found guilty of "improper and unprofessional conduct," and reprimanded accordingly.

The Mineral Water Hospital, Bath.

THE Governors of this ancient charity have found it necessary to decrease the number of beds owing to lack of funds. The hospital is really a national institution, being very little used by patients from Bath itself owing to the intentions of the original Founder. Of the 149 inmates at present in the building, 148 come from other towns, cities and rural districts throughout the British Isles, and the Hon. Treasurers feel that they are justified in appealing for national help at the present juncture. Most other hospitals are largely supported by annual subscriptions; but in consequence of the liberality of this institution in admitting patients without subscribers' recommendations, it is to a great extent deprived of that source of income, the total annual subscriptions received last year from private persons being only about £600. We trust that this appeal, which is made officially by the Mayor of Bath, will meet with the success it merits.

The Irish Medical Schools and Graduates' Association.

THE autumn meeting and dinner of this Association will be held at the Hotel Cecil on Wednesday, November 27th, at 7.30 p.m., when the special guests will be Sir James Digges La Touche, K.C.S.I., and Sir Shirley Foster Murphy.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society, was held in London on the 8th inst., Dr. de Havilland-Hall in the Chair. The accounts presented showed that the business of the Society continued in a very satisfactory condition. During the summer months the sickness claims had been somewhat in excess of the expectation, but during the month of October they were few in number, and for the most part of short duration. A small addition has been made to the list of those permanently incapacitated, and so drawing what are practically life annuities, but not more than was expected from the growing number and increased age of the members. Prospectuses and all further particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London.

THE opening meeting of the Dublin University Biological Association will be held to-morrow evening, when the President, Dr. Robert J. Rowlett, will deliver an address on "Biology and Therapeutics." Among the speakers will be Sir Arthur Chance, Drs. W. St. C. Symmers, Walter G. Smith, and J. B. Coleman.

THE Earl of Rosebery presided at a quarterly meeting of the trustees of the Hunterian collection, held at the Royal College of Surgeons on November 13th. Sir Douglas Powell (President of the Royal College of Physicians), Mr. Henry Morris (President of the College), and Dr. David Ferrier, Dr. J. Mitchell Bruce, and Professor G. Sims Woodhead were present at the meeting. Sir John Tweedy was elected a trustee of the collection in the vacancy occasioned by the decease of Sir Joseph Fayrer. The trustees adopted a resolution expressing regret at the death of Professor Stewart, and recorded their appreciation of his services as conservator of the museum.

LORD BALFOUR OF BURLEIGH recently attended a meeting at Birmingham in support of the scheme for providing the Queen Alexandra Sanatorium at Davos. His lordship said the object was to provide accommodation for English-speaking patients of small means suffering from curable forms of pulmonary disease. The site had been purchased, and a large sum raised, but £15,000 to £16,000 more were required. Sir Oliver Lodge proposed a resolution commending the sanatorium to the sympathy and support of the public, and it was decided to open a fund in the town.

PASS LISTS.

Royal College of Surgeons.

THE following candidates, having passed the required examinations and conformed to the bye-laws, have been admitted members of the Royal College of Surgeons of England:—

Wm. S. Alderson, M. Thos. Ascough, Wm. Thos. Briscoe, B.A., Arthur Burrows, Martin Camacho, Jas. R. C. Canney, B.A., J. A. Clark, Robt. M. Coalbank, J. L. Cock, G. G. Collet, B.A., Wm. W. Cook, Robt. Crawford, B.A., N. C. Davis, G. H. Davy, B.A., E. J. de Verteuil, R. L. E. Downer, G. W. Dryland, B.A., N. A. Eddlestone, E. P. Evans, F. P. Fisher, A. E. Foerster, A. E. G. Fraser, T. R. Glynn, B.A., P. H. G. Gosse, Morrice Greer, J. E. Hailstone, M.A., J. P. Hastings, H. J. Henderson, E. B. Hinde, B.A., F. G. Hitch, E. Le R. Hodgkins, M. J. Holgate, F. H. Holl, J. G. Ivers, W. M. Jeffreys, B.A., Robt. Knowles, B.A., Percy Lang, A. N. Leeming, K. A. Lees, B.A., W. H. Leigh, R. McC. Linnell, B.A., H. N. Little, B.A., E. W. Lowry, J. A. Master, W. L'Estrange Mathews, M. H. E. R. Montesole, Benj. Moore, H. H. Moyle, A. T. Nankivell, W. F. Neil, Donald North, E. E. T. Nuthall, B. H. Palmer, B.A., John Parkinson, D. G. Perry, C. H. L. Petch, A. G. Peter, L. L. Phillips, Montagu Phillips, B.A., E. S. Phipson, M. D. Price, M. J. Rattray, Alfred Richardson, C. M. Rigby, C. F. Robertson, L. P. Sanders, E. A. Saunders, S. MacK. Saunders, G. B. Scott, R. B. S. Sewell, B.A., F. M. Smith, P. L. Stallard, B.A., R. H. E. Stevens, K. H. Stokes, H. D. Thomas, G. G. Timpson, S. N. Tiwary, G. W. Trigg, B.A., R. W. S. Walker, B.A., G. D. H. Wallace, A. L. Walters, W. W. White, Reg. Willan, R. T. Williams, G. E. Wilson, A. L. Yates, and A. P. Yonge, B.A.

A Diploma of Fellow has been granted to Lieut. R. H. Bott, I.M.S., and Diplomas for Licence in Dental Surgery to E. W. Cooke and D. B. Franks.

Royal College of Surgeons in Ireland—Dental Examination.

THE following candidates have passed the necessary examination for the Licence in Dental Surgery:—P. J. Bermingham, T. J. K. Bradley, C. J. Hyland, F. Leniham, M. S. Philson, and R. P. Thomson.

The following have passed the primary part of the examination:—W. Bennett, N. A. Clarke, C. A. Furness, and L. P. Vernon.

Trinity College, Dublin.

THE following candidates passed the Final Medical Examination, Part II., Michaelmas, 1907:—Medicine.—William S. Thacker and George F. Graham (passed on high marks); Frank R. Seymour, Bethel A. H. Solomons, Edward C. Stoney, Edward J. H. Garstin, Julian B. Jones, Henry J. Keane, William H. Sutcliffe, William Knapp, John H. Waterhouse, Albert E. Wynne (*satis respondit*).

NOTICES TO CORRESPONDENTS, &c.

☛ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

M. R. S.—The mortality, direct and indirect, of acquired syphilis, when properly treated, is stated not to exceed 4 or 5 per cent. These figures apply to normal and otherwise healthy individuals, of regular habits. In elderly, inebriate, and exhausted subjects the proportion is probably tenfold. It is obvious, in view of the difficulties inherent to such researches, that the statistics can only be very approximative.

METRICUS.—It may interest you to know that the English penny piece weighs exactly ten grammes and the halfpenny five grammes. Inasmuch as an ounce is approximately the equivalent of thirty grammes, three pennies may be taken to represent one ounce and so on.

MINOR.—We should not recommend our correspondent to consent to the clause mentioned in the partnership deed.

COMA.—Many things have been tried, but we think the only treatment for diabetic coma which has shown any particular result is the administration of sodium bicarbonate. The drug may be given by mouth or by hypodermic injection, preferably the latter. The theory on which it is given is that of excess of acid (chiefly β-oxybutyric acid) in the blood.

W. R. M.—The statement you refer to is one of the standing type that find their way into medical text-books, and then become stereotyped by being adopted by one author after another. No one quite knows how they arise. We should be very sorry to defend it ourselves.

INCOME TAX REMISSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—By the Finance Act, 1907, passed in the last session of Parliament, the 133rd Section of the Income Tax Act, 5 and 6 Vict., c. 35 (whereby relief was granted whenever the profits of the year of assessment fell below the average) was abolished. All persons who shall receive a notice of charge for the current year (1907-8) desiring to appeal against the same on the ground that it is excessive, are required to give notice of appeal within the time set out on such notice of charge, failing which the Commissioners of Taxes will not at any time thereafter entertain any application to have such assessment amended. Persons whose profits for the year ended prior to the 6th day of April last fell below the average should at once take the necessary steps to claim repayment of any sum they are entitled to.

Yours, etc.,
THE INCOME-TAX ADJUSTMENT AGENCY.
E. MONTAGUE,
Sec.

London, E.C.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 20TH

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Paper:—Mr. J. W. Gordon: Mercury Globules as Test Objects for the Microscope.

ROYAL METEOROLOGICAL SOCIETY (Institute of Civil Engineers, Great George Street, Westminster, S.W.).—7.30 p.m.: Papers:—The International Balloon Ascents, July 22nd to 27th, 1907. Reports by Mr. W. H. Dines, Mr. J. E. Petavel, Mr. W. A. Harwood, Capt. C. H. Ley, and Prof. W. E. Thrift. Discussion of the Meteorological Observations made at the British Kite Stations, 1906-1907 (Miss M. White, Mr. T. V. Pring, and Mr. J. E. Petavel).

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m.: Inaugural Address: Sir Steuart C. Bayley.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. R. Johnson: Clinique. (Surgical.) 5.15 p.m.: Lecture: Mr. D. Armour: Head Injuries.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

THURSDAY, NOVEMBER 21ST.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. A. W. M. Robson: Pancreatic Catarrh and Interstitial Pancreatitis in Relation to Catarrhal Jaundice and also Glycosuria.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Throat Operations (Mr. Carson). 5 p.m.: Demonstration at the Mount Vernon Hospital, Hampstead, N.W.:—Dr. J. E. Squire: Selected Chest Cases.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—8 p.m.: Chesterfield Lecture:—Dr. M. Dockrell; Acne Vulgaris in its Three Stages: I., Comedo; II., Indurata; III., Necrotica.

HOSPITAL FOR SICK CHILDREN (Gt. Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. Kellock: Torticollis.

FRIDAY, NOVEMBER 22ND.

ROYAL SOCIETY OF MEDICINE (EPIDEMIOLOGICAL SECTION) (20 Hanover Square, W.).—8.30 p.m.: Paper:—Dr. M. Coplans: Medical Inspection in Schools: The Gloucestershire Scheme.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Dr. H. Tilley: Clinique. (Ear.) 5.15 p.m.: Lecture:—Dr. D. Ferrier: Atrophic Paralyses.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Outpatient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Demonstration:—Dr. W. Wingrave: Clinical Pathology.

TUESDAY, NOVEMBER 26TH.

ROYAL SOCIETY OF MEDICINE (THERAPEUTICAL AND PHARMACOLOGICAL SECTION) (Apothecaries' Hall, Blackfriars, E.C.).—4.30 p.m.: Dr. James Cantlie, M.B., F.R.C.S.: Some Tropical Diseases and the Remedies Required for their Treatment and Prophylaxis; Dr. William Murray, F.R.C.P.: Therapeutics of Indigestion.

Appointments.

EVERSHED, A. R. F., M.R.C.S., L.R.C.P.Lond., Honorary Ophthalmic Surgeon to the Brixton Dispensary.

HOLLAND, EARDLEY L., M.D. Lond., F.R.C.S.Eng., Obstetric Registrar and Tutor to King's College Hospital.

INNES, JOHN, M.B., C.M.Aberd., Medical Officer to the Aberdeen Dispensary.

M'EWAN, THOMAS DUNCAN, M.B., Ch.B.Glasg., Junior Assistant Physician to the Royal Asylum, Glasgow.

READ, A. W., M.R.C.S., L.R.C.P.Lond., Clinical Assistant to the Chelsea Hospital for Women.

SHAPLAND, JOHN DEE, M.D.Durh., Honorary Medical Officer to the Brixton Dispensary.

SHAW, CHARLES JOHN, M.D.Edin., Senior Assistant Physician to the Royal Asylum, Glasgow.

Vacancies.

Cornwall County Asylum, Bodmin.—Third Assistant Medical Officer. Salary, £140 a year, with board, lodging, etc. Applications to Medical Superintendent.

Shanghai Municipal Council.—Assistant Medical Officer of Health. Salary, £580 per annum. Applications to Messrs. John Pook and Co., 63, Leadenhall Street, London, E.C.

Windsor and Eton Royal Dispensary and Infirmary.—House Surgeon. Salary, £110 per annum, with residence, board, laundry, and attendance. Applications to Geo. P Cartland, Secretary.

West Riding Asylum, Wakefield.—Assistant Medical Officer. Salary, £150 per annum, with apartments, board, washing, and attendance. Applications to the Medical Director.

Royal National Hospital for Consumption for Ireland.—Resident Medical Officer. Salary, £300 per annum, with house. Applications to Hon. Secretary, 13, South Frederick Street, Dublin.

Births.

JOBSON.—On Nov. 11th, at Trelyon, Ilford, the wife of T. Battersby Jobson, M.D., of a daughter.

SOMERSET.—On Nov. 12th, at Stoneleigh, Mansfield Road, Reading, the wife of Edward Somerset, M.R.C.S.Eng., L.R.C.P. Lond., of a son.

SYMONS.—On Nov. 14th, at Officers' Quarters, Queen Alexandra Military Hospital, Millbank, S.W., the wife of Major F. A. Symons, R.A.M.C., of a daughter.

WISE.—On Nov. 14th, at 206, Burrage Road, Woolwich, the wife of H. M. Wise, M.B., of a son.

Marriages.

DENT—LEWIS.—On Nov. 15th, at St. Peter's Collegiate Church, Wolverhampton, Howard Henry Congreve Dent, F.R.C.S., eldest son of the late Joseph Henry Dent and Mrs. Dent, of Merivale, Edgbaston, to Olive Mary, daughter of Rowland W. Lewis, J.P., of Penn Croft, near Wolverhampton.

GIBBINS—DIX.—On Nov. 18, at St. James's, Paddington, Kenneth Mayoh Gibbins, M.B., B.S.Lond., M.R.C.S., L.R.C.P., of Holmdale Parkstone, Dorset, eldest son of B. T. Gibbins, of Ilkley and Tunbridge Wells, to Anne Mary, daughter of the late Thomas Tucker Dix, of Wells, Somerset.

TOOTH—CHILVER.—On Nov. 12th, at the Parish Church, Midhurst, Howard Henry Tooth, M.D., C.M.G., of 34, Harley Street, London, to Helen Katharine, second daughter of the Rev. Charles S. Chilver, of Gate House, Midhurst.

Deaths.

COOKSON.—On Nov. 12th, at St. Kitts, Carysfort Road, Boscombe, Jane Grace, wife of Samuel Cookson, M.D., late of Stafford.

HUTCHINSON.—On Nov. 15th, in London, after a long illness, Sir Charles Frederick, M.D., of Mayfield, Sussex, youngest son of Dr. Hutchinson, of Nottingham and Scarborough, in his 58th year.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, NOV. 27, 1907. No. 22

NOTES AND COMMENTS.

The "Brown Dog" and the Students. THE news of the raid on the "brown dog" memorial at Battersea by some University College and Middlesex Hospital students, and its disastrous termination, is very poor reading, as likewise are the accounts of the subsequent demonstrations and processions. It is of course not legal, and therefore not politic, to smash property that does not belong to one, however offensive such property may be. The law will not even allow a sanitary authority to break up the most pestilential doss-house without full compensation to the owner out of the ratepayers' pockets; it matters not that his property has been a cause of sickness and death to dozens. So, too, it is possible apparently to write on an erection in a public place an insult to a learned corporation, calculated to bring it into disrepute and contempt, and to enjoy the full protection of the law. It is difficult to believe that the Council of the University College have not taken legal advice on the matter, and been advised to let it rest; but we should have thought ourselves that taking the words of the inscription and the action of the erection of the memorial very good grounds for a libel action are shown. The dog is alleged to have been "done to death in the laboratories of University College," and though the phrase may possibly not bear an exact legal interpretation, it is always used as a synonym for murder. Murder is illegal killing, and whatever may be said about the dog's death it was destroyed in a perfectly legal and regular manner. That, to our mind, might constitute one count in a libel action. The second is like unto it. It is said the dog "endured vivisection extending over more than two months." The *suggestio falsi* is obvious enough. We should go further and say that the ordinary interpretation of the words would be that the animal was operated on continuously for two months, which, though absurd to instructed persons, would not be to the folk likely to see most of the memorial.

Its Serious Side. IT may be wise of University College to take no action if not assured of winning on legal grounds, but it is impossible for the Council to be surprised at its students feeling and resenting the insult. They must also remember that the London newspapers, which regard undergraduate "rags" at Oxford or Cambridge as pardonable youthful frolics, even if a policeman or two be maimed seriously, always characterise in the harshest terms any evidence of similar spirit in a London student. The Battersea memorial is a standing menace to the reputation for good conduct that London medical students have earned for themselves for the last twenty or thirty years, and the point is one for the authorities fully to consider. The whole "brown dog" incident constitutes one of the most disgraceful pages in the anti-vivisection movement, and that we fear only because it happened to be sifted in a court of law. The story was a grave perversion of facts; it was repeated to a large audience without inquiry or confirmation, and was disproved before a jury. Without one word of regret for the utter want of truth and ingenuousness characterising the whole affair, the anti-vivisectionists subscribed £2,000, the amount of the damages rewarded for the libel, to recompense the defendant, and actually proceeded further to accentuate their want of shame by erecting a memorial to commemorate the incident. It is bad enough that a section of faddists should behave thus, but that the official representatives of a London borough should receive the statue especially bearing such an inscription is almost incredible.

Vice-versa. WE wonder how the young men of Battersea, who take a pride in their borough and their civic representatives would like it if (say) University College erected in Gower Street a monument to a bullock, with some such inscription as the following:—

"In memory of the dun bullock, which was cruelly mutilated by being castrated, without any anæsthetic, in order that his flesh might taste better at the Mayoral dinner at Battersea in November.

"Also in memory of 5,000 bullocks done to death in Battersea every year for the gratification of man."

We hope that they would have sufficient good feeling not only to resent the insult, but to recognise that, whereas the barbarous operation was performed not only without anæsthetics but for no necessary purpose, that animal experimentation provides the children of their borough with the only means whereby they can efficiently be helped to recover when attacked by diphtheria. At any rate, we could hardly be astonished if demonstrations in force were made against such a memorial, and we suspect that those journals who regarded the suffragette riots with amiable tolerance, and now denounce the students with corresponding vigour, would find plenty of excuses in "provocation."

"Self-Protection." SINCE the days of Madame Blavatsky and Mr. Edmund Garnett's revelations there has been a great slump in Indian mysteries and cults, and our American friends have taken the opportunity to foist a little occidental philosophy upon us in the shape of Christian Science. The essence of both cults seems to be unlimited credulity, and (at least) a moderate income. The poor, however little their education, curiously enough are seldom effected by these typhoons of ecstaticism, whether they blow from East or West. But on the stage of esoteric things enters a fresh heroine, a Hindoo lady, bearing the very Eastern name of Madame Cavalier, who seems destined to win fame again to her neglected country. Recently she gave a lecture on the very original title of "Self-protection from Adverse Suggestions." From the description of the lecture it seems that she started away with the usual preamble about earth-planes and spirit-spheres, but the cloven hoof soon exhibited itself beneath the silk gown, and the full tide of doctors not knowing their own business and Madame Cavalier knowing a great deal about it, was let loose. The adverse suggestians from which people are to protect themselves, are not, apparently, those thrown out by Madame Cavalier, but diseases. It is true, says the prophetess, you suffer pain—there, at least, she has the start of the Christian Scientists, for people always like others to know when they suffer—but you can always get rid of it by calling only on the "leader." The leader may be Mahomet or Christ; it really does not matter; they will be effectually protected by an "electric band of light." The room is said to have been filled with devotees, and we shall probably soon have a church, temple, or mosque erected for their convenience.

Alcohol and Cirrhosis.

It is a curious fact that it needed the excited comments of the lay Press on two cases of hepatic cirrhosis in children to stir the medical profession to look up the evidence connecting that condition with alcoholic excess. At any rate, the attention of the profession has been seriously directed to a scientific question as the result of outside agitation. Whatever may have been in the minds of most, Dr. Welsh Branthwaite's intimation that among 8,000 drunkards with whom he has been brought into contact during the last five years, he has never come across one case of cirrhosis, is a little disconcerting. Dr. Branthwaite says he has seen congestive liver enlargement and functional disturbance after drinking bouts, but they have always subsided under rest and temperance. It is probably true that only a small proportion of drinkers get cirrhosis, and that cirrhosis is not only caused by alcohol, but it may seriously be questioned whether it be actually alcohol itself or some other constituent in intoxicating drink which causes the fibrosis. The attention directed to the subject will do much good if it result in clearing up the enigma, but as an instance of the harm that the questioning of a belief like this may do we may instance an article in the *Daily Telegraph* of November 18th, in which the writer uses the discussion to show that alcohol may not be such a bad thing after all, and that it is unreasonable to attempt to limit the supply of drink to people till more is known about it. Happily, even people who are not doctors recognise that alcohol has some dangers, even if cirrhosis of the liver is not the most prominent.

LEADING ARTICLES.

DO MEDICAL MEN ASSIST IN THE SALE OF PROPRIETARY MEDICINES?

The mind of the medical profession, as a whole, is sufficiently well made up on the point of the evil of proprietary medicines to warrant some plain speaking as to the matter. In approaching such a subject it becomes at once apparent that many diverse interests are concerned, and that there are manifold phases which demand careful investigation in order to arrive at anything like a sound perception of their relative meaning. The truth of that proposition will be readily recognised after a brief survey of the operations of the drug trade, both wholesale and retail, of the proprietary medicine trade, of the professional journals and publications, of the newspapers and journals that profit by advertisements, of all these as regards capitalists, public and medical profession. The tangled issues involved in that combination present a problem that requires tact, knowledge, and a strongly judicial spirit for its solution. Among these complexities arises the question whether medical men do not in some instances play into the hands of the proprietary system which they regard with so much disfavour. This doubt has been sugested by an important work recently issued by the Pharmaceutical Society of Great Britain, under the title of the "British Pharmaceutical Codex." The scope of the volume may perhaps best be conveyed to medical readers by designating it as a kind of enlarged and comprehensive extra-pharmacopœia. Its appearance has given rise to a vast deal of criticism in the ranks of the pharmacists themselves. We are not here concerned with the list of inaccuracies inevitably connected with a work of so great dimensions, dealing as it does with a vast array of details. Nor does there seem great pertinency in the complaint that the volume in question to a great extent partakes of the nature of a compilation. So far as the medical profession is concerned one of its most important features consists in the definition of a great number of drugs or combinations of drugs sold under fancy names, so that any practitioner can, by reference to the Codex, see exactly what he is ordering, and, if necessary, replace it by the corresponding drug from the British Pharmacopœia To take an instance which is unlikely to injure delicate susceptibilities, it is well known that boracic acid forms the basis of various dusting and face powders, sold under a variety of catchpenny titles. Let us for a moment assume that a medical man entertained the unlikely intention of prescribing one of those proprietary dusting powders. By turning to the particular trade name in the Codex he would at once learn that it consisted of, say, boracic acid, starch, and oxide of zinc, whereupon he might write his own formula. It may be argued that he would be doing an injury thereby to the proprietor, but it is difficult to understand what exclusive right can be claimed in a combination of well-known drugs, such as are ordered by medical men daily throughout the length and breadth of the land. It would be easy to multiply instances almost indefinitely, but it will serve the purpose if readers are asked to think for a moment of the various proprietary forms in which aloes, jalap, permanganate of potash, cascara sagrada, the salicyl compounds, chloral and opium are sold to the public. We suggest that medical practitioners who order such compounds are playing into the hands of the traders in proprietary medicines. The position of the Pharmaceutical Society with regard to the matter may be gathered from the following quotation, taken from the preface to the Codex. "Special attention has been devoted to the nomenclature of substances of definite composition which are known under a variety of names, and it has been considered desirable to describe such substances under brief, more or less descriptive names, which have, in some instances, been specially devised for the purpose. Reference is made to trade-protected names and other commercial designations of such substances in footnotes to the respective monographs, though prescribers will prefer to encourage the use of names which everyone is free to use. Trade names, as a rule, can only be legally applied to the products of firms or individuals in whom proprietary rights in those names are vested, and the attention of dispensers is particularly directed to the fact that when a medicament is ordered under a proprietary trade name, it is not permissible to substitute a similar product to which that trade-name does not legally apply." The subject is alive with possibilities, and medical men will do well to inform themselves upon the prescribing of simple drugs under fancy names thus brought within the range of practical politics by the issue of the Codex.

CLIFFORD v. TIMMS.

The last phase of Clifford v. Timms was completed in the House of Lords last week, when the Court, consisting of the Lord Chancellor, Lord Halsbury, Lord Macnaghten, and Lord Atkinson, gave judgment for the respondent without even calling on his counsel. We can only say that if the House of Peers gave equally convincing proof of its business acumen in political matters, there would be little demand for its reform from either party in the State. To the non-legal mind it has always been a marvel how any lawyer could have advised that there was any ground for action, the breach of the partnership agreement being so obvious and above board. But the marvel was rendered still more staggering when the case was heard before Mr. Justice Warrington, and decided against the defendant. At the trial a great deal was done to "side-track" the issue by raising the unnecessary question as to whether the decisions of the General Medical Council are binding on other statutory authorities, and it must be confessed that it is a pity that the House of Lords could not have settled the matter once for all in giving their judgment. We have no reasonable doubt what the decision would have been after the views that were expressed in the Court of Appeal, although Mr. Justice Warrington in the lower court, in our opinion, erred strangely for a man of his calibre. But although, as we say, we regret the point was not settled by the House of Lords, we commend heartily the broad outlook taken by their lordships and the business-like way in which they refused to be drawn by the red herring dragged across their path. The whole point of the case was whether the action of Mr. Clifford, in starting an institute of dentistry, worked by unregistered dentists under the supervision of himself and his family, who were registered dentists, and advertising the institution by such methods as decrying the competency, and even making insinuations against the characters of English dentists, was guilty of professional misconduct, because, if so, Mr. Timms was at liberty to break his partnership deed. This exceedingly simple issue led to all this litigation and fuss, when to the ordinary man it must have been palpable that if professional misconduct, as apart from private misconduct, means anything, it means precisely conduct of the character perpetrated by the appellant. The Lord Chancellor, in giving judgment, in which all the members of the court concurred, brushed aside the question of the statutory authority of the decisions of the General Medical Council as being a matter of indifference to the issue, and merely said that it having been shown that Mr. Clifford had sanctioned the form of the advertisements, professional misconduct was *ipso facto* proved. We heartily congratulate Mr. Timms, and trust that now he has severed himself from these gentry, he will enjoy the pursuit of his art by the regular methods which all that is best in the spirit of dentistry seeks to establish in the practice of that beneficent art.

CURRENT TOPICS.

The Victory at Bristol.

The determined and united action of the Staff of the Royal Infirmary at Bristol and the practitioners of the neighbourhood has met with the success that must always follow such action, namely, by the withdrawal of the propositions of the other side. We understand that the settlement has been arrived at by a process of give and take, and the terms will probably be announced in due time. But the matter for rejoicing at the present moment is that it has been demonstrated again that no town or country can afford to flout medical opinion, and that if medical men are firm, reasonable, and united they cannot be overridden by any body in the land. The victory is especially gratifying in that most of the committee of the Royal Infirmary are strong men of much local prestige, and the issue was one which offered considerable temptations to such medical men as did not see eye to eye with their colleagues in the matter. But in all these matters it must be borne steadily in mind that the undermining of the influence of a colleague or band of colleagues is a dangerous policy which is sure sooner or later to react on the interloper. Happily in the present instance there has been nothing but loyalty, and the staff have vindicated their right to be regarded not as subordinates to the Committee of Management, but as their colleagues and coadjutors. The staff would not have dreamed of laying down how many charitable committees members of the Board might serve on; it was no less ridiculous for the Committee to attempt to lay down a similar rule for the staff.

The Memorandum of the Medical Department of the Board of Education.

The Board of Education, through the Medical Department, have issued the promised memorandum on the medical inspection of school children. As we have indicated before, the policy of the Board as now more definitely declared, is to work the inspection through the medical officer's of health department, and, according to the memorandum, he is to be the chief executive officer, having such assistants and subordinates as his authority thinks necessary. The practical and economical convenience of this policy is obvious; its dangers equally so. Let us hope that in practice the latter will prove below expectation. The words of the memorandum are brave and, we are sure, sincere. "One of the objects of the new legislation is to stimulate a sense of duty in matters affecting health in the homes of the people; to enlist the best services and interest of the parents; and to educate their sense of responsibility for the personal hygiene of their children. . . .

It is in the home, in fact, that both the seed and the fruit of public health are to be found." All that is as it should be, but if this process of enlistment and stimulation is to be successful, it will require an amount of patience and tact among the officers appointed which are very personal to the individual. The Board have decided to have but three inspections of the children—namely, on joining, at about the third year after joining, and at about the sixth year after joining; and they hope that the parents will be present at the first inspection. We fancy that the last suggestion is one of the most salutary.

The Medical Student of To-day.

Curiously enough, only a few days have elapsed since the appearance in our columns of a comment upon the docile and exemplary conduct of the medical student of to-day. Within the past week some extraordinary ebullitions have taken place in London, arising out of a police-court prosecution of certain medical students, the facts of which are noted elsewhere. The demonstrations have been of an innocent but somewhat tumultuous nature. Members of various schools have rushed in shouting procession through the streets, bearing in one instance the figure of the Highlander taking snuff, which has appeared on previous occasions, and in another instance carrying aloft an effigy of the unpopular magistrate. Such conduct is indefensible, if only on the ground of the potential disorder of a serious kind that is inseparable from emotional outbreaks of this kind conducted *coram publico*. At the same time it will hardly be denied by police and public that some ground of provocation was altogether wanting in the affair. Indeed, the whole demonstration may be regarded as the harmless protest of a number of high-spirited youths, who imagined they were labouring under long-standing provocation. Their conduct was one of righteous indignation rather than of the latent or inherent rowdiness which some of the journals have rather ungenerously imputed to them.

Patent Medicines in the Antipodes.

The Commonwealth Government of Australasia seem resolved to attack the evils of the patent medicine trade with stern determination. A short Bill has been announced, to be introduced as a supplementary measure to the Commerce Bill, in order to confer greater powers of control over the importation of those proprietary goods. The advent of this Bill is announced in the *Australasian Mail* of November 17th. It will enable the Minister of Customs—directly, and without any loophole for equivocation being given—to insist upon the labels of the bottles of all imported medicines bearing such indication as to the nature of the contents as the Minister may deem necessary. The necessity of supplementary legislation was forced upon Sir William Lyne, who had imagined that sufficient power was already conferred by the Commerce Act, but he had subsequently been informed by the Crown Law Officer that to remove all possibility of disputes a special Bill was necessary. By this step the stern rebuke is offered to the United Kingdom, whose worthless and dangerous wares are thereby excluded from Australasian shores. The irony of the situation, interpolated as it is amid an economical tariff strife, may be accepted as a solid contribution to those who protest against the patent medicine traffic in the United Kingdom. If the Colonies one and all reject these noxious imports from the Mother Country, they will inflict a deadly blow against a ruthless social monster.

Tradesmen's Wrappers.

The pitfalls to health are so manifold and various that our eyes must necessarily be shut to many of them. At the same time there are a certain number that can be dealt with summarily if once haled before the bar of public opinion. Among these minor dangers come the newspaper coverings often used by tradesmen to wrap up butter, cheese, bacon, fish and other articles of food. It is simply appalling to reflect on the myriads of microbes that must be adherent to the surface of an ordinary newspaper that has been in the hands of readers and in many strange places before being stored in the tradesman's shop. One marvels that such a practice should ever have been permitted by a long-suffering public to exist. It is tolerably certain that when once recognised the dawn of better things will quickly arise in the shape of clean, white, preferably sterilised wrappers around all articles from butterman, grocer, provision vendor, fishmonger and other dealers in articles of food. Indeed, the better class tradesman has already abandoned the filthy newspaper for the attractive white wrapper.

Sandow as Physician.

Let the cobbler stick to his last, and let the professional strong man attend to his own legitimate business. Mr. Eugene Sandow was the first to show what marvels could be accomplished by the systematic cultivation of the human muscles. No one can complain if he advocates his methods of physical culture as conducive to health, and even indirectly curative in various minor troubles, just as golf, or rowing, or riding, or other exercise is an aid to health. But when Sandow plays the physician and claims to cure a long list of maladies, including dyspepsia, nervous diseases, gout, rheumatism, paralysis, heart, chest, lung and "various other complaints," then we see no particular reason why he should not be classed with other quacks. Presumably in all or nearly all cases he makes his own diagnosis, a fact that at once vitiates hopelessly his statistics both of the nature of cases and of cures. How is a man to distinguish between a trivial and a most serious form of dyspepsia? In the latter event it may be, of course, merely symptomatic of such things as cancer, advanced disease of liver, heart disease, or consumption. If Sandow claims to cure "dyspepsia" with his exercises he is by inference asserting his ability to deal with any of the causes mentioned. This single instance suffices to show the self-sufficient and unblushing temerity with which the amateur and untrained physician is prepared to tackle any ill that human flesh is heir to.

Sarcoma and the Compensation Act.

The relation of malignant disease to industrial occupation is likely to give rise to a goodly number of keenly disputed cases under the new Workmen's Compensation Act. Already two cases in which sarcoma was alleged to have followed injury have been decided in favour of the workmen. In one instance the sarcoma affected the jaw, and was said to have been the result of an accident. In the second a leg was amputated for sarcoma in the lower end of the femur, said to have resulted from an injury some three months before the growth was recognised. Curiously enough the majority of the text books on surgery are silent as to the possible or probable relation of sarcomatous growths to traumatism. There are two notable exceptions, however, in Bland Sutton's book on "Tumours," and in Sir Frederick Treves's "System of Surgery," both of which accept the theory of traumatism as a cause, at any rate, in periosteal and by implication in endosteal forms of sarcoma. As other cases of the kind are certain to occur from time to time, it is highly desirable that surgeons should endeavour to formulate some fairly definite conclusions in this interesting point of etiology. From the circumstances of the case it is difficult to establish absolute data, but with further extended and concentrated observation it should not be impossible to arrive at an authoritative verdict as to the balance of probabilities in this alleged relationship.

Property in Dead Bodies.

Arising out of our note on "Property in Museum Specimens," in the issue of November 20th, in which we said that "it might be possible to prosecute a scientific enthusiast of such a kind [*i.e.*, one who stole museum specimens] for stealing the glass jar and spirits, and even for damage to the jars," a correspondent reminds us of a curious incident. In the days of body-snatching every "sack-em-up" was aware that his avocation, dangerous as it was, was not illegal if he merely captured the naked body, whereas removal of any of the grave-clothes was punishable. In the latter half of the eighteenth century, when Cornelius Magrath, the famous Irish giant died, Robinson, the Professor of Anatomy in Dublin, is reported to have said to his class:—"Gentlemen, I have been told that some of you in your zeal have contemplated carrying off the body. I must earnestly beg of you not to think of such a thing: but if you should be so carried away with your desire for knowledge that thus against my expressed wish you persist in doing so, I would have you to remember that *if you take only the body, there is no law whereby you can be touched, but if you take so much as a rag or a stocking with it, it is a hanging matter*" ("James Macartney," by Alex. Macalister. 1900. p. 16-17). Needless to say that in a few days the good professor himself dissected the body, and Magrath's skeleton still remains in the museum of Trinity College.

Indian Methods for Delirious Patients.

The sentence of death recently passed upon a Cree medicine man, in the Keewatin territory, reveals a curious practice in that remote tribe. The trial, which was noticed in the *Times* of October 28th last, originally extended also to an old chief, but the latter strangled himself while in custody. The charge was that of having put a delirious woman to death. One of the witnesses confessed that another murder of the same kind had taken place three weeks later, he himself helping to hold down the victim—a sick man who had been brought by his wife from another tribe simply to be put out of the way. The medicine man was condemned to death, but recommended to mercy on account of his ignorance. Immediately after the trial a party of mounted police set off on the 400-mile journey to Gurry Lake, in order to arrest several Indians concerned in another murder of the same kind, which is believed to have been the twenty-sixth committed within the last twenty years. The putting to death of delirious persons is probably due to a belief in their demoniacal possession. It is not so many generations ago that our own treatment of lunatics was almost equally primitive in practice. A plausible explanation of the matter is that the natives desire to get rid of helpless persons who consume their share of a limited supply of food, although themselves unproductive. In certain savage tribes, as in Patagonia, it is a recognised custom to destroy the aged and useless members of the community.

PERSONAL.

H.M. the King has sent his annual subscription of £100 to the Middlesex Hospital.

Mr. R. A. Bickersteth was elected Surgeon to the Liverpool Royal Infirmary on November 21st.

The Master of the Apothecaries' Society, Dr. George Wilks, took the chair at the Lord Mayor's Day dinner given by that company.

Dr. F. Henry was, on November 19th, at a meeting of the Liverpool Select Vestry, appointed Medical Superintendent of the Highfield Infirmary.

Sir R. Douglas Powell, President of the Royal College of Physicians of London, opened the Tuberculosis Exhibition in Belfast last Friday.

Dr. Sidney P. Phillips will take the chair at the annual dinner of the Harveian Society at the Imperial Restaurant to-morrow (Thursday) at 7.30 p.m.

Mr. Rockefeller has given £520,000 for the permanent endowment of the Institute for Medical Research which he founded at New York in 1901.

Sir Alfred H. Keogh will hold conferences with the medical profession at Exeter and Plymouth early next month on the proposed medical service for the Territorial Army.

Lady Theodora Guest has presented to the Westminster Hospital, at Shaftesbury, a fully equipped operating room as a memorial to her mother, the late Marchioness of Westminster.

Prince Ranjitsinji has given Rs.1,000 to the Jamsetjee Jeejeebhog Hospital at Bombay as a token of the skill and devotion shown him during his late illness by a nurse from that institution.

Sir William Bennett, K.C.V.O., Consulting Surgeon to St. George's Hospital, has been elected President of the Incorporated Institute of Hygiene in place of the late Sir William Broadbent, Bart.

The Faculty of Medicine of London University have appointed Professor Ernest Henry Starling, M.D., B.S., F.R.C.P., F.R.S., to be their representative on Senate for the remainder of the period 1905-9, vice Dr. Lauriston E. Shaw resigned.

Dr. G. E. Cartwright Wood, Bacteriologist to the Laboratories of the Royal College of Physicians and Surgeons, London, has been appointed by the Metropolitan Asylums Board as Bacteriologist at their establishment at Belmont, at a salary of £600 a year.

A CLINICAL LECTURE

ON

LINGERING LABOUR; ITS CAUSES AND TREATMENT. (a)

By JAMES MORRISON, M.D.Lond.,

Hon. Physician Accoucheur Farringdon Dispensary and Lying-in Institution.

GENTLEMEN,—First of all, I want to show you this Barnes-Galabin-Simpson variety of forceps, the only forceps on the market which allows the manipulations of two pairs of forceps in a single instrument.

In regard to our subject for this afternoon, lingering labour, I would like to remind you of some of the points, because I am constantly being called in to cases of lingering labour in which there should be no difficulty. By "lingering labour" I mean labour where there is no mechanical obstruction to the birth, both passages and passenger being normal, and the cause of such labour is some fault in the forces. In the primipara the full time which should be taken for the whole confinement is 24 hours, and in the multipara 12 hours. That, of course, is a very long time, particularly in general practice, and therefore the second stage in the multipara is often cut down to nil. You may say that for the primipara the first stage is 16 hours, and the second 8 hours; and in the multipara 8 hours and 4 hours respectively. But you can never do wrong by waiting in the case of the primipara. In multipara you can cut it down to 4 hours justifiably by putting on forceps. It is an unwritten rule at Queen Charlotte's to cut short the second stage in a multipara after two hours by putting on forceps—that is to say, lingering labour, where there is no obstruction, but where the pains are wanting or are insufficient, and so the labour is delayed over the average time.

The causes of delay in lingering labour may be classified as those due to the mother's general condition, causes in the uterus, and causes in the passages; there are also causes on the part of the child. If the child is too large, the labour will be an obstructed one. All sorts of debilitating diseases will lessen the mother's expulsive force; anæmia, lung troubles, and the wasting due to starvation are the common ones. I do not propose to go into these to-day. You must always be on the look-out for diverticula and pendulous belly. If you stand the patient up, you may find that, instead of the child pointing downwards and backwards towards the coccyx, the abdominal walls are pendulous, and the child more or less looks upwards and backwards. The absence of pains is due to what is called primary uterine inertia. The tonic contractions belong to obstructed labour, not to lingering labour. Primary inertia means that the pains are weak from the beginning; the woman has never had pains strong enough to expel the child. That very seldom occurs in the primipara, but in the multipara it is common. In pendulous belly there is a lack of abdominal pressure owing to weakness of the recti. Secondary uterine inertia means that the pains have been strong, but that they have then got weaker and gone off. The commonest causes of these are, 1st, that the woman has not been properly taught how to bear down; 2nd, she is not well under the doctor's control; she is tossing about, and refuses to do anything she is told, and when the pains come on she screams. She does not make use of the pains, the child does not advance, and after a time she naturally becomes exhausted; then the pains get weaker, and pass off. When this happens, many men, having watched the case for several hours, bring up their forceps and put them on. That is quite the wrong thing to do, for the result is post-partum hæmorrhage. They do not know what to do, so they put on a binder, and hope for the best. Many years ago, when I was a "locum," I had three or four of these cases in one week. The practitioner had come back to the surgery, and shortly afterwards received a message that the woman was bleeding. He said he was too busy to go—would I mind? Some of them were nearly moribund, and in each case he had put on forceps because he could not wait. The uterus is clogged, and you cannot get any stimulation of it; so after the child is delivered you perhaps use a hot uterine douche, but it will not contract. The reason is that the nervous arc is broken at the nerve end-plates, which are clogged up with the products of the constant contractions. You can give smelling-salts, put the child to the breast, apply cold water to the abdomen, and give a uterine douche, but the placental site will bleed because of this clogging with the products of nervous waste due to the continual strong pains. In those cases there is nothing to do but plug the uterus.

In regard to the ovum itself, one very common cause of lingering labour is premature rupture of the membranes; perhaps it is the cause in nine cases out of ten. In the posterior cases the lower uterine segment is not properly filled by the head, the woman bears down before the cervix is opened, and there is, therefore, premature rupture of the membranes. And later on, the head not being properly flexed, the occiput remains behind, and you have to put on forceps. I want to devote a good deal of attention to-day to the subject of the premature rupture of membranes. The membranes may be too adherent round the internal os, which you notice more in placenta prævia. Then there is over-distention of the uterus, so that the uterus cannot get a "purchase" on the child. Other causes are hydramnios and twins. In that the delay is in the first stage; everything goes right after the membranes are ruptured. It is common for the first stage to be delayed 24 or 36 hours, and I have seen cases in which the pains have continued for three days, but were not strong enough to open up the cervix.

Let us consider the commonest cause of lingering labour—the premature rupture of membranes. The treatment depends on the stage at which you meet with it. If the membranes are ruptured with the cervix half an inch or so thick, the treatment differs from that where the cervix is open and the walls thin. If you get the case early, and the cervix is still thick, and is not fully dilated, do not put on the forceps. Never put on forceps with an undilated cervix. Use de Reeve's (?) bag. Absolutely the best use of this bag is in premature rupture of membranes. Before the cervix is open, the uterus turns the dilating force into an expulsive force, and the uterus pushes the child on to the cervix, the cervix gets emptied and closes up again, and there is a hard, rigid, contracted cervix, with spasm. To prevent that, put in this bag and replace the membranes. In that way you save hours, because the labour now goes on in the normal way. You can alter the tension of the bag by pulling on the tube, and when the bag comes out, the os will be sufficiently dilated for the bag to pass. If you have not this bag, use an ordinary penny air-ball blown out and tied on to a catheter, and an ordinary pair of forceps will be sufficient for introducing the bag. This bag can be introduced into a cervix which admits two fingers; afterwards loosen your forceps and turn on the tap. Blow it up with water, and as it fills see that this is well inside the cervix, and afterwards extend it up as far as it will go. Then take out the forceps, which can be removed separately. If you have a difficulty in getting the bag inside, fix the anterior lip with a volsella. With the Barnes bag it is necessary to have a number of them, and therefore the risk of sepsis is increased. You only want one such bag as I show you; it is easily sterilised. Sometimes these cases of premature rupture come off without trouble, but the majority of them cause delay; therefore do not wait until you replace the bag of membranes. If you cannot introduce the bag because the cervix will not admit two fingers, you must wait, and, while waiting, give chloral, a 1-drachm dose by the bowel. It is supposed to have a specific action on the cervix, and I think it has. I have given drachm doses hundreds of times, and I have never had a bad result from it, though some people say chloral is not a safe drug to use. You can repeat in ½-drachm doses. If you have a case in which you have not put on your de Reeve's bag, and you are sorry for it, and where labour has been going on longer, and the uterus has emptied itself of its liquor amnii, the cervix is still in front of the head, and very often the anterior lip is nipped between the child's head and the pubes, and therefore gets œdematous; the pains are very great, causing the woman to shriek; those cases want treatment quite differently. You find a thin os, and the child's head will descend before the osseous canal is open. It is of no use putting in a bag, because if you begin to push up the child you will risk rupturing the uterus. You give the woman chloroform, and it acts like a charm—perhaps in ten minutes the whole case is over. The head is rammed down on the cervix, and causes it to be irritated and go into spasm, and that causes the painful contraction. By giving chloroform you relieve the pressure, and take the head off the cervix, and the cervix opens up. You can either put on forceps or let it deliver naturally, but the case is over. Chloroform acts better and quicker in these cases than opium.

(a) Delivered at the Medical Graduates' College and Polyclinic, Chenies Street, W.C., on Monday, July 8th, 1907.

NOTE.—The Author's corrected proof had not been received at the time of going to Press.—EDITOR.

There is a similar condition, but not so marked, where the pains are not so great and the descent is greater. The cervix is not so thin, and the os more open, but the swollen anterior lip protrudes from the vulva. There is a plum-shaped mass. Do not cut it off as a polypus. The treatment for that is, while the pains are off, put your finger between the head and the anterior lip, and try to stretch the cervix over the child's head. Between the pains there will be a distinct relaxation of the uterus, and the woman will allow you to press the anterior lip up.

Primary uterine inertia due to other causes must be treated in the ordinary way. Several things are often overlooked at confinements. The woman does not have rest and food. In primiparæ, very often two or three days before labour commences she has not been eating or sleeping. These two important points must be looked to. If the pains are not strong, give her plenty of liquid nourishing food and sedatives, opium being the best. When she awakes the pains will be stronger, and the birth will probably take place. The bowels and the bladder must be seen to. A loaded rectum was a common cause of lingering labour, but nowadays the bowels are better looked to. Still, a loaded bladder is a common cause, and later on it causes hæmorrhage. The doctor is continually in the room, and the woman has had her pains to think about, and even if she has thought about her bladder, she has not liked to say she wanted to empty it. If after that there is nothing in the way, the os is opened, and the labour is not coming off, the question is—when are you to interfere by putting on forceps? In a multipara, where there is nothing wrong with the passage or with the passenger, you are justified in putting on the forceps after two hours. You do so, not to pull the child out, but to help the pains. So you must pull with the pains, and relax between them. If the head is sticking in the upper part of the pelvis, put on axis-traction forceps. If the child is sticking in the lower part, put on the ordinary ones. I advise you, for general practice, in these high cases, to put on axis-traction bars. With the ordinary forceps you are not pulling far enough back, and that makes all the difference as to whether the child comes down easily or not. Never put forceps on a primipara, however many hours you may have to wait. If you can get a woman through her first confinement without a temperature and without cutting, she will get through it without being a chronic invalid. If the ordinary married woman has instruments at her first confinement, she always seems to have something wrong with her afterwards. There is only one justifiable exception to this, and that is when the head sticks at the bony outlet, at the narrowest part of the pelvis. If the head does not advance, you are justified in putting on forceps. You pull the child's head a little bit past with one good tug, and immediately take off your forceps; don't attempt to bring the head over the perinæum. In the primipara you wait half an hour before putting on the forceps to see if the head advances. When the head is once through the bony outlet, it will never slip back. Bathe the perinæum with hot fomentations. Some doctors say they do not believe in fomenting the perinæum, but others do. Many of those who do not believe in it have applied a little warm water by means of cotton wool once every half-hour. That, of course, has no effect. You want a big diaper or plug of cotton wool, the water as hot as she can stand it, and soak the perinæum and right back on to the buttocks. If you look where the lines of stretching took place after the child is born, you find them on the buttocks and thighs, showing that those parts ought to be softened. In carrying out your softening, do it for half an hour, then give it ten minutes rest, and then go on for another half-hour. Let the head come forward and go back as often as you like, but each time it will come a little further. Whenever you get that backward and forward process on the perinæum, labour never stops, secondary uterine inertia does not come on at that stage, and the more often it does that the safer it is for the perinæum.

With regard to unfavourable positions, of course the great bugbear is the posterior case. You do not diagnose the posterior position until the membranes have been ruptured, and perhaps the head has descended well into the pelvis. But if you diagnose the posterior position only, before the rupture of the membranes, or while the head is still at the brim, or the cervix not fully dilated, it is justifiable to attempt to rotate the posterior cases into anterior cases. And I advise you to always give chloroform, and always introduce the whole hand into the vagina, seize the occiput, and pull it round to the front. You are working above the brim, and therefore you can do it. When you have got the occiput in front, keep it there. With the other hand rotate the anterior shoulder to the opposite side of the abdomen. If you do not do that it will get into the same position again. When the head is engaged in the pelvis, it will not move again, but if you have not got the shoulders round, the child will swing back again. The posterior fontanelle should be much lower than the anterior. As soon as you recognise that you have a posterior case, therefore, you push up the forehead and carry out what I have described.

Ordinary Unreduced Occiptio-Posterior Cases:—The treatment for this condition is either to put on forceps and pull the head down the perinæum, with the occiput behind, and then take off the forceps and allow the occiput to rotate to the front, and again put on the forceps in order to extract the head, or else put on the forceps the wrong way up, and as you pull down allow the forceps to rotate right round; in other words, anticipate the rotation of the occiput to the front. In putting on the forceps, introduce the left blade with the left hand, and with the edge of your finger on the blade rotate it round. Do not do this by the handle alone; you guard the blade from injuring the uterus by means of the hand. Do similarly with the right blade. I remember particularly a case in which an attempt had been made for several hours to deliver, and finally the instruments were laid out in readiness to do craniotomy. But they had not tried what I am now describing. I put the blade on in the way I have mentioned, and, with moderate pulling, I got the head down. It was a 12 lb. baby. I can assure you it is an extremely good tip for those cases.

The only other point about lingering labour is breech labour. In this kind there is nearly always a lingering labour, because you have the child coming the wrong way—that is, with the head and shoulders up above. Most of the force of the uterus is exerted in squeezing, like squeezing a pip between the fingers, but with the larger part above; the result of the squeezing is to force the child upwards instead of downwards. In a breech case leave the membranes intact as long as possible; do not rupture them, even if they appear at the vulva, because even when the breech has passed through the cervix the cervix is not dilated enough to allow the head to pass. Secondly, remember you have to deliver the child artificially, so you must be prepared to deliver. And you ought to have a systematic way of delivering the breech. When the breech comes down to the umbilicus, you must yourself start to deliver, because when the child has reached that spot it has only four minutes to live, because the placenta is beginning to be detached, and the child has half left the uterus. First look for the arms, and always be prepared to pull down the extended arms, the posterior arm first; then turn the child right round until the anterior arm becomes the posterior. Next deliver the head, and do not attempt to pull the head out until you have passed your hand in. Then put your fingers into the mouth. The head must come down transversely from the pelvis; pull it down from the brim to the floor. Don't attempt to rotate the child until the head is on the floor. You must not turn the back to the front immediately the shoulders are born, though that is the usual thing one sees. All the time you are delivering the breech you should either be pushing on the uterus or getting someone else to push down, because the more you pull from below the more you tend to extend the legs and arms. Deliver the breech always with the woman lying in the dorsal position across the bed. Secondly, always give chloroform if you possibly can, because it is painful to pass the hand in alongside the child's body. Of course, if more than four minutes have elapsed after the child has reached the umbilicus, and before it is born, you do not cease your efforts, but try to resuscitate the child. I have seen a child pulled round when it has been 20 minutes afterwards.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by R. W. Philip, M.A., M.D., F.R.C.P., F.R.C.S.E., Physician and Lecturer on Clinical Medicine, Royal Infirmary, Edinburgh. Subject: "Exophthalmic Goitre and Myxœdema."*

ORIGINAL PAPERS.

TUBERCULOSIS IN CHILDHOOD AND ITS RELATION TO MILK. (a)

By JOHN M'CAW, M.D., R.U.I., Etc.,

Senior Physician to the Belfast Hospital for Sick Children.

DURING the past few years, and especially at the present time, the tuberculosis question has engaged and is engaging the attention of the medical profession in all countries. A campaign is being carried on against tuberculosis which has already resulted in much benefit, and bids fair to eventually stamp out the disease completely. Whether or not this highly desirable result will be attained in our time is very doubtful, but it is satisfactory to know that the means by which the disease is generated and spread are well known, and that prevention is not impossible.

The medical profession in Ireland have not been behind-hand in this campaign. The large amount of tuberculosis existing in Belfast has been very forcibly brought out by means of letters in the local Press, and especially by statistics submitted by the various witnesses who appeared before the Health Commission. Further, the Registrar-General of Ireland, in his annual report for the year 1906, points out that out of a total of 74,417 deaths registered no fewer than 11,756, or 15.8 per cent., were due to tuberculous disease. Of the total number of 11,756 deaths, the number dying from phthisis (pulmonary tuberculosis) was 8,933. Of this total, 1,072 died between the age of 15 to 20 years; the deaths from 20 to 25 years numbered 1,444, and from 35 to 45 years they numbered 1,557. The report of the Superintendent Medical Officer of Health of Belfast shows that during the year 1906 1,015 deaths were registered in Belfast as caused by phthisis, and 395 from other forms of tuberculous disease.

Finally, the Registrar-General for Ireland points out that, while in England the death-rate for all forms of tuberculous disease has declined from 3.3 per 1,000 in 1864 to 1.6 per 1,000 in 1905, and in Scotland from 3.6 per 1,000 in 1864 to 2.1 per 1,000 in 1905, it has in Ireland risen from 2.4 per 1,000 in 1864 to 2.9 in 1904 and to 2.7 per 1,000 in 1905 and 1906. With these figures before me I think I am justified in saying that in no country is it more desirable to pursue a vigorous campaign against tuberculosis than in Ireland, and in no city in the United Kingdom is a better opportunity afforded for studying and fighting the disease than in Belfast. Our position, therefore, with regard to the large amount of adult tuberculosis existing in Belfast, is well known and assured, and to it I need not further refer; but what about tuberculosis in childhoood? As a separate enquiry this aspect of the question has been but lightly touched upon, and I shall endeavour, as far as possible in the time at my disposal, to supply the omission in what follows.

My connection with the Belfast Hospital for Sick Children for the past twenty years has given me exceptional opportunities for studying the disease, and I shall now place before you, as shortly as possible, the main points with regard to tuberculosis in childhood, and lay special emphasis upon the connection which exists between tuberculosis and cows' milk. In order that my remarks may be quite clear and readily followed, I shall discuss the subject under the following heads:—(1.) What amount of tuberculosis in children exists in Belfast? (2.) What types of the disease are met with? (3.) What connection exists between tuberculosis and cows' milk? (4.) What can be done to prevent or cure the disease?

1. WHAT AMOUNT OF TUBERCULOSIS IN CHILDREN EXISTS IN BELFAST?—In conversation with the physicians and surgeons attached to children's hospitals I find a general consensus of opinion that tuberculous disease of one kind or another forms a very considerable part of their work in these institutions, and Professor Holt states that autopsies on children dying from all causes under 15 years of age, show the presence of tuberculosis estimated by various observers at from 14 to 40 per cent. I think the statement may safely be made that a large amount of tuberculosis exists among children. That this opinion is well founded, I shall now endeavour to support by a few statistics. At the Children's Hospital, in Queen Street, during the quinquennial period 1902-06, 26,193 cases were treated, and tuberculous disease in some form was met with in almost 20.0 per cent.—to be accurate, in 19.99 per cent. of them. Of this total, 4,049 were treated as in-patients in the wards, and 28.52 per cent. of them were tuberculous, while 22,144 new cases were treated in the out-patient department, and 18.26 per cent. suffered from tuberculosis in some form.

The interesting question arises: How do we in Belfast compare with other cities in regard to the amount of tuberculosis met with in children? To arrive at an answer to this question I have examined, on exactly the same basis, the returns of the cases treated at various hospitals, as follows:—

(a) An address delivered at the Opening Meeting of the Ulster Medical Society.

Belfast Hospital for Sick Children	—**No. of intern patients, 828; No. tuberculous, 28·74 per cent.**
Ulster do. do. do.	—**No. of intern patients, 247; No. tuberculous, 30·36 per cent.**
Great Ormond Street, London...	—**No. of intern patients, 2,876; No. tuberculous, 27 per cent.**
Royal Edinburgh Hospital ...	—**No. of intern patients, 1,968; No. tucerculous, 20 per cent.**
Manchester Children's Hospital	—**No. of intern patients, 1 999; No. tuberculous, 21·3 per cent.**
East London do. do.	—**No. of intern patients, 2,054; No. tuberculous, 24·3 per cent.**
Glasgow do. do.	—**No. of intern patients, 1,177; No. tuberculous, 27·95 per cent.**

This table shows a wonderful agreement amongst the returns of these hospitals as to the amount of tuberculosis met with. My firm conviction is that all children's hospitals meet with much the same amount of tuberculosis, and that that amount is very large.

2. What Types of the Disease are Met With?—A glance at the statistics which I have given will be sufficient to demonstrate the fact that a certain number of the cases of tuberculosis met with at the children's hospitals are deemed suitable for treatment in the medical wards, while others are more properly sent to the surgical side. From this, then, one might say that there is a medical as distinguished from a surgical form of tuberculosis; and while this is true enough, still it is not sufficient, nor does it satisfy the question.

One of the most noteworthy deductions from the statistics is the preponderating amount of surgical tuberculosis met with when compared with that seen by the physician, and this point I wish very specially to emphasise, as having a most important bearing on causation and treatment. If the returns of the hospitals mentioned be examined, it will be found that the cases treated on the medical side consist of phthisis and meningitis, spinal caries and general tuberculosis; while on the surgical side the surgeon is deluged with chronic abscesses, tuberculous joints, lymphadenitis, and chronic ulcers. But it should be noted that many of the cases treated in the medical wards would be more properly classified as surgical—such, for instance, as lupus, spinal caries, etc.—which, if added to the surgical figures, would still more emphasise the preponderance of surgical over medical tuberculosis. These facts suggest the question, is the disease as seen by the physician only another form of that met with by the surgeon, or are they different types of the same disease, and caused by a bacillus of a different species?

Recently the theory has been put forward that tuberculous affections of the human body are divisible into two types:—(*a*) a type caused by tubercle bacilli from the human, and called the "typus humanus"; and (*b*) a type caused by tubercle bacilli from the cow, and called the "typus bovinus." These bacilli are varieties of the same species, but they give rise to quite distinct and different lesions, according to the method of infection. In the first (or human) type, the bacilli are inhaled in dust, and find a lodgment in the apex of the lung. From this site of infection the disease may spread and cause secondary infection of the intestines, or set up a tuberculous laryngitis. In the second (or bovine) type, the disease is conveyed indirectly by means of tubercle bacilli taken into the body in raw milk, meat, etc. Here the infection is carried to the intestines and mesenteric glands, and gives rise to tabes mesenterica, tuberculous peritonitis, tubercle of the pelvic organs, tuberculous lymphatic glands, tuberculous bones and joints, lupus, tuberculous meningitis, or acute miliary tuberculosis. Much may be said in support of this theory; and I will content myself at present by pointing to the enormous amount of surgical tuberculosis met with at an age when cow's milk is largely availed of—indeed, is the chief article of diet—as a circumstance of the highest moment, and also to the following extracts from the report of the Royal Commission on Human and Bovine Tuberculosis. In that report (page 10) the effects of feeding calves with the bacillus of bovine tuberculosis are set forth as follows:—In each of six cows, whose udders had been made tuberculous by intra-mammary injection, the calves were allowed to suck for varying periods. In one case only was general tuberculosis produced. In all the other five calves killed, after being kept alive from 74 to 363 days, the tuberculosis was for the most part limited to the intestines and mesenteric glands. Fourteen calves were fed with tuberculous milk, the number of bacilli ingested varying from one to ten millions. None of these calves showed when killed anything more than tuberculosis limited to the intestine and to the mesenteric or ileo-colic glands; in one case tuberculous lesions were found in the pharyngeal glands. In other animals the results are no less striking. Thus a quantity of milk from a tuberculous udder produced in each of two pigs tuberculous disease of the mesenteric and ileo-colic glands. In goats, feeding sometimes produced a generalised progressive tuberculosis; at other times the disease was limited for the most part to the mesenteric and adjoining glands. In anthropoid apes, a chimpanzee was fed for a week with tuberculous milk, the number of bacilli given being estimated roughly to be 100 millions. It was killed when very ill, 100 days later, and showed generalised progressive tuberculosis; the intestines and associated glands were tuberculous, and there were also tubercles in the lungs, thoracic glands, spleen and kidneys. Another chimpanzee received 10 million bacilli, tuberculous milk being the medium. It died 144 days afterwards, with tuberculous ulceration of the intestines, and caseous or caseo-calcareous lesions in the mesenteric and mesocolic glands. The tuberculosis was, therefore, limited. These experiments, then, in the anthropoid ape, an animal so nearly related to man, are of the highest importance, and point clearly to the fact that when the dose of bovine tubercle bacilli taken into the system is large, a generalised tuberculosis, starting from the intestines and mesenteric glands, is set up; whereas when the dose is moderate, the affection may remain confined to the intestines and mesenteric glands, which in time may extend to other glands and bones and joints. Here, then, I submit is evidence sufficient to support the contention that the large percentage of tuberculosis met with in children is bovine, and caused by the ingestion of bovine tubercle bacilli in milk, meat, etc., and that this form of tuberculosis is chiefly surgical. But this theory goes a step further. It is affirmed by some that these two types of the disease are more or less antagonistic, so that a child when it becomes affected with bovine tuberculosis absorbs an antitoxin, which protects it against the human type of the disease, and similarly the human type renders it either less liable to be attacked by, or immune against, the bovine bacillus. In support of this contention the rarity of pulmonary tuberculosis in association with tuberculous glands, or joints, or bone disease is pointed to; and the further fact is relied upon, namely, that the vast amount of tuberculosis met with in the child is surgical, the result of infection with bovine bacilli, and also that the adult or human type of the disease is quite rarely met with at an early age.

To carry this argument to a logical conclusion: if this theory be correct, then human serum, or tuberculin R., should be beneficial when used for surgical or bovine tuberculosis; and, *vice versa*, bovine serum should be beneficial in tuberculosis of human type. Much evidence could be adduced in support of this contention, and my experience, but more especially the experience of surgeons, is, that in limited tuberculous lesions of a surgical nature the injection of tuberculin R. is followed by favourable results. Dr. Nathan Raw, of Liverpool, whose work in this connection has been very extensive, writes me to say that he has obtained the most gratifying results from the use of these serums, and, after long observation of clinical cases, and extensive laboratory work, he is convinced the theory is sound. I cannot, however, now wait to discuss this point further, but I should like to make the suggestion that during the session an evening might be very profitably devoted to a discussion of this subject. The third question to be answered is:—

3. What Connection Exists Between Tuberculosis in Children and Cows' Milk?—As I consider this to be a very important part of my subject, I should like to emphasise its importance as much as possible, for two reasons—*first*, because the connection is a very close and vital one, as I shall endeavour to prove; and, *secondly*, because no serious attempt has yet been made by the authorities to determine the amount of tuberculosis existing among dairy cattle, much less to adopt such measures as are necessary to stamp out bovine tuberculosis. In what has gone before, I have shown that a large amount of tuberculous disease exists amongst children. Let me now draw your attention to the fact that the disease appears at a time of life when cows' milk is the main, or almost the main, article of diet. These two statements taken together are sufficient to establish a *prima facie* case against cows' milk. Further, I have shown that tuberculosis in children is very largely of the surgical type—that is, it is chiefly glandular, and almost certainly due to the bacillus of bovine tuberculosis which has been taken into the system in food. In support of this the following definite pronouncement of the Royal Commission is of the highest moment. On page 36, paragraph 66, of their report is the following:—"There can be no doubt but that in a certain number of cases the tuberculosis occurring in the human subject, *especially in children*, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis; and there can also be no doubt that in the majority at least of these cases the bacillus is introduced through cows' milk. Cows' milk containing bovine tubercle bacilli is clearly a cause of tuberculosis, and of fatal tuberculosis, in man. Of the 60 cases of human tuberculosis investigated by us, 14 of the viruses contained the bovine bacillus. If, instead of taking all these 60 cases, we confine ourselves to cases of tuberculosis in which the bacilli were apparently introduced into the body by way of the alimentary canal, the proportion of cases of bovine infection becomes very much larger. Of the 60 cases investigated by us, 28 possessed clinical histories indicating that in them the bacillus was introduced through the alimentary canal. Of these, 13 contained the bovine bacillus. Of 9 cases in which the cervical glands were studied by us, 3, and of the 19 cases in which the lesions of abdominal tuberculosis were studied by us, 10, contained the bovine bacillus. These facts indicate that *a very large proportion of tuberculosis* contracted by ingestion is due to tubercle bacilli of bovine source. A very considerable amount of disease and loss of life, *especially among the young*, must be attributed to the consumption of cows' milk containing tubercle bacilli, . . . for the bacillus of bovine tuberculosis can readily, by feeding as well as by subcutaneous injection, give rise to generalised tuberculosis in the anthropoid ape, so nearly related to man, and, indeed, seems to produce this result more readily than in the bovine body itself." After these weighty words it is quite unnecessary for me to labour the point further, and, indeed, it would be a waste of your time were I to do so. This pronouncement of the Royal Commission establishes a close and clear connection between cows' milk and tuberculosis in children, and must be considered final.

4. Finally, What Can be Done to Prevent or Cure the Disease?—With regard to the first part of the question—how can we prevent tuberculosis in childhood? I think I may safely say a general opinion exists that our best hopes for eradicating the disease lie in the direction of preventing it, and accordingly measures adopted for prevention must be energetically pursued. Two eminent opinions have been expressed on this point from which we may obtain guidance, namely, that of Professor Koch, who lays stress upon the transmission of the disease by contagion, especially by means of the respiratory organs; and that of Professor Von Behring, who is of opinion that tuberculosis in children is principally disseminated through the alimentary canal, and he sees a fruitful source of danger to children in the tuberculous nature of much of our milk supply. I think both these pronouncements are true, but I hold strongly that the latter theory is the more important one as regards children. Acting upon Koch's opinion it is necessary that children be kept apart from those suffering from pulmonary tuberculosis, whose breath and sputa are loaded with infectious germs. This has been recognised in Germany, where visits are made to the houses of consumptives, children are removed, when this is possible, from such surroundings, directions are given and patients are taught the most efficient means of disinfecting and disposing of their sputa, and the necessity for keeping their clothes, beds, furniture, and floors clean. Such means as these constitute a powerful factor in limiting the area of the disease and diminishing its virulence. Then much good has resulted from convalescent homes in the country, holiday camps, and forest schools. The country homes are simple but suitable buildings put up somewhere in the woods to which children may be taken and kept for the entire day. At these homes everything is conducted upon strictly hygienic lines, from the proper cleansing of the children to the furnishing of a suitable dietary, and the enforcement of physical exercise.

Coming now to Von Behring's view that tuberculosis in children is principally disseminated through the alimentary canal, I believe we have here the most important factor in the tuberculosis of children. Many eminent authorities in this country adhere to this view, and have given expression to the opinion that the bacilli found in these cases are most commonly of the bovine type, and gain entrance into the system by means of the milk of infected cows. It may here be asked, what amount of bovine tuberculosis exists? The report of the Royal Commission on Tuberculosis states that "of all animals slaughtered for food in Great Britain and Ireland those of the bovine race seem to be more largely affected with tuberculosis than any other." In the absence of statistical information as regards our own country, the report proceeds to show that, in Leipzig, of 9,303 cows slaughtered, 4,048, or 43.51 per cent., were tuberculous. The proportion of such diseased cattle in English cow-houses, which has been publicly and authoritatively stated to be about 30 per cent. by the late Professor MacFadyean, is, therefore, probably not excessive. In the year 1901 there were 1,887,414 milch cows in England, and 4,102,061 in the United Kingdom. Thirty per cent. of these means upwards of 560,000 tuberculous cows for England alone, and nearly 1¼ millions for the United Kingdom. If 5 quarts of milk be allowed as a fair average yield per day for each cow, then 6,250,000 quarts of milk, the daily yield of tuberculous cows, are consumed each year in the United Kingdom. Again, it has been calculated, and is admitted, that tuberculosis of the udder exists in 2 per cent. of dairy cows in the United Kingdom; this means that some 20,000 cows with active tuberculosis of the udder are to-day contributing to our milk supply, and some 100,000 quarts of milk teeming with virulent bovine tubercle bacilli are consumed each day in the United Kingdom.

When it is remembered that even one diseased udder is capable of disseminating a huge number of tubercle bacilli, the bare idea of the amount of possible human tuberculosis from the milk of so immense a number of diseased cows is appalling. I regret I am unable to place before you any statistics bearing upon the prevalence of tuberculosis in cattle supplying milk to Belfast, but the following figures, taken from the report of the Medical Officer of Health of Manchester, Dr. Nevin, are interesting in this connection:—During the year 1904, 432 samples of milk were examined, the number of farmers represented in the total being 318. Of these 318 farmers, 188 reside in Cheshire, and 21 of them (or 11.17 per cent.) sent tuberculous milk; 83 live in Derbyshire, and 5 of them (6.02 per cent.) sent tuberculous milk; 14 reside in Lancashire, and 1 of them (7.14 per cent.) sent tuberculous milk; 8 reside in Yorkshire, and 2 of them (25.00 per cent.) sent tuberculous milk. Are we in Belfast any better off in regard to the number of diseased cows supplying milk than Manchester? My firm belief is we are not. I am confirmed in this opinion from what I have seen when visiting some of the dairies within the city, and that much tuberculous milk is purveyed in our midst I think admits of no doubt. It is clear, therefore, that a large amount of tuberculosis in cattle exists, and the connection between the disease in cattle and tuberculosis in childhood having been established, it follows, if we would prevent the disease in children, the first and most important step is to stamp it out in cattle. In considering how this may be done it is necessary to remember that in tuberculosis, before the formation of tubercles in any part of the body, there is a stage of the disease of unknown duration during which the bacilli multiply and circulate throughout the body. To regard the disease as beginning with and being localised in tubercular formations is to fail to recognise the bacillary stage of the disease, and is therefore wrong. This pre-tubercular stage can only be detected by means of the tuberculin test; therefore, it becomes imperative that this test be applied to all dairy cattle, and that every cow reacting to this test be withdrawn and the carcass destroyed. To ensure success, however, compulsory and universal application of the principle is necessary. Fair compensation for the loss to the stock-owner should be granted; and, probably, the sum of money that would be required for this purpose is the main objection to the enforcement of the measure by the Government. In the year 1865-66 an outbreak of cattle-plague occurred in this country, which involved the death of 233,000 head of stock. And what took place? The first consideration was the stamping-out of the disease as quickly as possible, and at any cost. But tuberculosis in animals is more widespread than cattle-plague has ever been: it is always present in our herds, whereas outbreaks of plague are few and far between; and, what is worst of all, tuberculosis causes a vast amount of sickness and suffering and death and despair, which cattle-plague does not do. Surely this most astounding condition of things will not be permitted to continue much longer. The public—and, more especially, we members of the medical profession—should now and at once insist, both on hygienic and economic grounds, that it is urgently necessary to stamp out this awful disease of tuberculosis in cattle. It is estimated that the disease in animals may be eliminated in a single year, and, if so, what a year of triumph that would be!

To protect children from the ravages of tuberculosis, the following rules may be formulated:—

1. The Notification of all Births Within Twenty-Four Hours.—This would enable health visitors to examine into the state of the child's surroundings; to have the child removed, or precautions taken, should any case of tuberculosis exist in the house; and to give suitable directions for the care of the child, and especially to encourage breast-feeding.

2. Complete Control of the Milk Supply by the State.—This should include the application of the *tuberculin test to dairy cattle*, and the removal of all such as react to this test; cleanliness in the collection of all milk, and in the transmission of it from the dairy to the consumer; the removal of dairies from the centre of large town and cities.

3. Medical Inspection of School Children and School Premises.—First, to detect and remove children who are actually ill or unfit to attend school; and, secondly, to ensure proper ventilation and sanitary arrangements in the schools, and to prevent overcrowding. The elementary principles of hygiene should be taught to even young children; to older children the principles of domestic hygiene and economy should be added.

4. Dwelling-houses in the poorer districts should be made more sanitary, especially with regard to the free access to them of sunlight and fresh air. Ireland is behindhand in this respect—a circumstance which may, in part, account for its high death-rate from phthisis. A levelling-up of the social and domestic conditions of the poor is urgently required; for of the 1,200,000 children born each year in the United Kingdom, fully one-fourth to one-third of them are born to want and squalor.

5. All advanced cases of phthisis should be segregated as far as practicable and treated in special institutions set apart for that purpose. Children who are allowed to live in the house with a consumptive are exposed to serious risk.

6. Notification of the disease should be compulsory. By this means health officers would know where the disease existed, and it would enable them to take suitable precautions against the spread of the disease by disinfection and other means.

With the second part of the question—*What can be done to cure the disease?*—I need not detain you long. I have said that the large proportion of tuberculosis in childhood comes within the purview of the surgeons, and with them the treatment may safely be left; for Belfast is fortunate in having a band of gentlemen second to none in the kingdom for operative skill and surgical acumen.

With regard to the use of tuberculin, the scientific investigations concerning it have placed in our hands a remedy of the greatest value. Unfortunately, the profession still feel a want of confidence in it, or a dread of its reaction, but it should be remembered that the use of tuberculin at the present time is very different from what it was when first introduced. Formerly tuberculin was administered by rule of thumb, and often with disastrous results; now, thanks to the brilliant researches of Sir A. E. Wright, and the discovery by him of the opsonic index, the dose of tuberculin, its effects, and the most suitable times for injection, can be regulated with scientific precision.

This discovery has in fact brought treatment with tuberculin within the realm of safe therapeutics, and the clinical success which has attended the employment of this treatment has firmly established its position as a remedial agent of the first importance. In addition to the use of tuberculin, our efforts to cure tuberculosis, or stay its progress, must include good and wholesome food, healthy hygienic surroundings, an abundance of pure air, and such drugs as cod liver oil in combination with the hypophosphites.

THE ABORTIVE TREATMENT OF SYPHILIS BY THE INTENSIVE METHOD.

By Prof. R. DUHOT, M.D.,

Director of the Dermo-Syphiligraphical Department at the Central Polyclinic, Brussels.

[Specially Reported for this Journal.]

The possibility of definitively cutting short an attack of syphilis by early intensive treatment has not so far been admitted. Perhaps it would be well for me to commence by putting in plain words what I really intend to convey by this term in order to avoid confusion. The word "abortive" in this connection must not be understood in the sense in which it might be interpreted after eradication of the chancre supposing, for the sake of argument, that this procedure really held out hope of attaining its object. Surgical treatment which would at the same time remove the cause and obviate the effects would indeed have been ideal, but unfortunately such is not the case.

The abortive treatment of syphilis in the sense I intend must be interpreted with a much wider scope, in fact, we must allow the term a certain elasticity. It consists of medical treatment which by energetic and rapid mercurialisation from the very onset prevents the generalisation of the spirochæte in the organism, shuts up the infection *in loco*, and restricts it to the chancre with limited glandular enlargement, subsequently weakening the infection until ultimate extinction in such wise that no secondary manifestation makes its appearance in spite of the closest search and observation.

In patients thus treated, therefore, we never get any roseola or general glandular enlargement, or alopecia, or mucous patches, or leucoderma, in short, none of the clinical symptoms by which we are enabled to diagnose the generalisation of the disease in the economy. Lymphocytosis in the cerebro-spinal fluid has also been absent in the cases that have been observed. It is indeed the curative and preventive properties of mercury pushed to their uttermost degree. It appears to me that the term "abortive" is justified by contrast with the other methods which admit recurrence as a general rule.

I have subjected altogether 134 patients to this mode of treatment, 120 men and 14 women, their ages varying from 16 to 36 years. Among these 134 cases six were doubtful, presenting certain ill-defined throat symptoms. The conditions of success of the abortive treatment are the following:—

(1) The treatment must be commenced before the twelfth day following the appearance of the chancre.

(2) The treatment entails the employment of injections of insoluble salts, or calomel, or what is more practical, grey oil, in intensive doses.

(3) The first course of treatment should be pushed to the utmost degree compatible with the resistance of the organism, and continued for not less than four months.

(4) The subsequent courses of treatment comprise shorter periods, on the lines of the chronic intermittent treatment of syphilis.

1.—THE TREATMENT TO BE COMMENCED BEFORE THE TWELFTH DAY.

Experience seemed to indicate the twelfth day as the limit for the certain, abortive treatment of syphilis, nevertheless I have myself successfully carried out the treatment in a case of chancre of 17 days' standing. That is a matter of judgment, and there is considerable difficulty in exactly establishing the extreme limit for the success of the treatment, and it is quite conceivable that other observers may find it feasible to extend this period. In any case the limit cannot possibly be the same in all patients, for no one will contest that the generalisation of the spirochæte takes place with very variable rapidity in different subjects, and that the conditions of microbial virulence and organic resistance must influence the duration of the period of generalisation.

The necessity for prompt treatment and the value of the preventive action of mercury, still questioned by some observers, are amply confirmed by the results of the abortive treatment. By pills and inunctions given from the onset we can at most hope to delay and mitigate the roseola, reducing it maybe to a few scant manifestations, whereas by a more energetic treatment, such as the abortive method, we may obviate it altogether. It must, however, be borne in mind that if instead of inaugurating immediate treatment we await the appearance of the roseola the same treatment, although applied with the same energy, will not succeed in jugulating the attack, and this fact, better than all the heresies put together, illustrates the capital importance of the epoch at which the treatment is begun. The possibility of cutting short an attack of syphilis had already been foreseen by my friend and master, Prof. Jullien, who has published several observations of the kind. All I have done has been to systematise his ideas, and I flatter myself that my efforts in that direction have been successful.

In early mercurial treatment there is one great rock ahead, viz., error of diagnosis. I believe, however, without arrogating to them the gift of infallibility, that syphiligraphers upon whom long experience has conferred the *tactus eruditus*, who scan with every care the incubation period and the appearances, have an immense superiority over the ordinary practitioner, and experience no hesitation under circumstances where others would be greatly embarrassed. In a really doubtful case I should be the first to hold my hand and await the appearance of the roseola. Of late, however, such cases have been getting rarer and rarer, and the chances of error have greatly diminished now that the recognition of the spirochæte affords us a new and unquestionable basis of diagnosis.

2.—METHOD OF APPLICATION AND DOSES.

If I early made up my mind only to use insoluble salts for injection in carrying out the abortive treatment, it was because experience had shown me that in practice this method alone possessed the qualities indispensable for the success of the treatment. I do not pretend that, theoretically, at any rate, inunctions and soluble injections might not attain the same end. But inunctions present certain drawbacks and shortcomings. They do not display the same activity in all subjects, and are open to various objections which it would be tedious to enumerate here. Daily injections of soluble salts become so irksome for the patient, and are often so painful in intensive doses, that these two methods can but rarely be found suitable in daily practice; moreover, they only imperfectly realise the abortive treatment. Soluble salts, moreover, present the very great disadvantage that they are too rapidly eliminated without having liberated their mercury constituent, and without having adequately permeated the cells of the organism. Indeed, for the results of the two to be made comparable, we should have to employ a method of uniform activity which would not be liable to numerous sources of error. Although the injection of insoluble salts is itself by no means exempt from drawbacks, it does assure the regularity of therapeutical effects as witnessed daily in our clinic which it will not occur to anyone to question at the present time.

The best method, then, is by the injection of insoluble salts, which enable us to obtain the desired results by methodical and scientific mercurialisation, without interfering with the patient's social and family life. Inasmuch as the abortive treatment ought not to be reserved for exceptional cases, but, on the contrary, should be employed whenever the opportunity presents itself, the therapeutical agent we make use of must be one readily accepted by the patient. The preparation that best fulfils this condition from every point of view is grey oil. It is, indeed, the preparation that appears to be most popular with syphiligraphers, who are in favour of insoluble injections, and their preference is justified by the fact that this preparation yields the best possible results, and has enabled me to carry out the abortive treatment in 134 instances, with only six doubtful cases.

3.—THE MAXIMUM INTENSITY OF THE FIRST COURSE OF TREATMENT.

Then, too, the method of insoluble injections realises better than any other the possibility of intensive treatment which is indispensable to its success. It is just when the virus is beginning to multiply that it behoves us to attack it with the greatest possible energy, and on the intensity of the first course of treatment will depend the ultimate course of the disease. It may be that in the subsequent courses of treatment less energetic means can be employed, and that inunctions and soluble injections may suffice to annul the virus once it has been mastered by the first course.

But for this first attack of the diathesis the application of mercurialisation must not be in the least attenuated. It must be pushed to the limit of organic resistance, and my experience has satisfied me that it is always necessary to give not less than 15 or 20 injections, entailing a course of about four months. The first three injections must be made at intervals of five days, the next three every six days, and the remainder at intervals of eight days. Each of these injections comprises a Barthelemy syringeful of grey oil at 40 per cent., which is equivalent to 0.14 centigramme of metallic mercury. These doses are calculated for adults of an average weight of 65 kilogrammes.

4.—TREATMENT TO BE CONTINUED ON THE LINES OF THE CHRONIC INTERMITTENT TREATMENT OF SYPHILIS.

During the two years following, I give ten or twelve weekly injections at intervals of two months. During the third and fourth years I give eight or ten injections at intervals of three months, but, as I shall explain later, I am by no means convinced of the necessity of treatment during the third, and especially during the fourth year, and if I have hitherto adhered to this plan it was merely in order to leave nothing to chance.

It may be objected by timid practitioners that there is more danger in pushing mercury in intensive doses than in allowing the development of a slight roseola; they may suggest that it would be safer to proceed with less haste rather than run the risk of mercurial intoxication. As a matter of fact, no such intoxication takes place provided one is careful to make sure of the integrity of the emunctories, and those who have visited my clinic have been able to satisfy themselves of the perfect tolerance of my method. Nor are we justified in employing this big word intoxication merely because there happens to be some slight discomfort, any more than we have the right to ascribe any lassitude and pallor exclusively to the influence of the treatment.

It may be conceded that mercury can never be a food, but neither will syphilis ever become a welcome disease, and assuredly we are more interested in ridding the organism definitely of such an enemy than in taking precautions lest the mercury should determine sundry slight inconveniences, which, moreover, are easily remedied. We see our patients during the intervals of the intensive treatment not only make good the weight they have lost, when there has been any loss, but even put on more flesh. This clearly proves that if there be any intoxication it is less than would be provoked by the generalisation of the virus of syphilis, so anæmiating in its nature, and of two evils it behoves us to choose the lesser.

Moreover, it would be absurd in the extreme to look at the matter from such a narrow point of view, and to overlook the fact that the roseola, as well as the local lesion, though admittedly of trifling gravity, is at the same time an unquestionable sign of constitutional infection. To allow the syphilis to run its course, says Jullien, when it is within your power to stop it, is to adopt an attitude of abnegation which nothing in therapeutics can justify, and the consequences whereof will weigh heavily on the whole subsequent course of the disease.

If the toxins of syphilis really play the part with which they are credited, would it not be supremely illogical to permit the development of these poison-producing agents of whose deleterious effects we are still imperfectly cognizant. The slight importance that used to be attached to the roseola has imbued many practitioners with another false idea, viz., that of making it a sort of criterium of the virulence of the attack and of regulating the energy of the treatment thereby.

Another very erroneous conception in respect of the syphilitic exanthem, which may explain the slight concern with which many regard it, is that syphilis at the secondary period is a purely cutaneous disease, oblivious of the fact that there may be many graver exanthemata than the one which is visible to the eye.

We know since Ravaut's works that roseola is not infrequently associated with cerebro-spinal lymphocytosis, and we are also aware of the refractoriness of syphilitic affections of the nervous system to medication. Can it therefore be a matter of indifference to allow the spirochæte, at the period of its first virulence, to attack the meninges and the cerebro-spinal centres the absolute integrity whereof is indispensable to the harmonious working of all the organs?

Lumbar puncture will render it possible for us to recognise the fact that the meninges are being involved, and if we are fortunate enough to have made the puncture early, we may be able to cut the process short. Moreover, it would be contrary to all clinical principles to allow an infective malady like syphilis to develop in the organism, and the routine practice of waiting for the appearance of the roseola before commencing treatment ought to be abandoned once and for all. It has, indeed, always been based on errors of observation. Lumbar puncture carried out on ten patients who had followed the abortive treatment only revealed physiological lymphocytosis, showing that the meninges had escaped injury.

In another patient who had had the roseola, puncture was made after his first intensive course of treatment, and microscopical examination revealed the past existence of lymphocytosis, characterised by the presence of degenerated deformed elements the nuclei whereof took the stain imperfectly. I am absolutely convinced that patients whose cerebro-spinal centres have been protected against the initial development of the diathesis will be less liable than others to subsequent syphilitic affections of the nervous system.

The abortive treatment should be employed at every opportunity, just as, speaking generally, the intensive treatment is applied to all syphilitics who are in a condition to support it. Not, however, that I wish to question the existence of benign forms of syphilis—benign, that is, either by reason of the diminished virulence of the organism or the enhanced resistance of the subject, but what I do deny absolutely is that there is any possible means of identifying these forms beforehand.

We may be asked whether the abortive treatment of syphilis will enable us to shorten the duration of the treatment. It is only logical to suppose that such is the case, although we are at present unable to bring any clinical proofs thereof. There are several patients whose treatment was abandoned after the second year, but as the problem is difficult and its solution wholly empirical, time alone will enable us to obtain the data on which to base a trustworthy conclusion.

If the old-fashioned methods of treatment, applied methodically during a period of four years, succeeded, in spite of many shortcomings, in reducing the proportion of tertiary patients in Professor Fournier's hands to 3 per cent., it is only logical to suppose that, as this result was attained in cases of syphilis in which constitutional infection had been shown by roseola and subsequent outbreaks, common sense would tell us that we can cure syphilis at less cost when it has, so to speak, been circumscribed from the commencement, and has been energetically fought throughout.

But the question acquires special interest, and demonstrates all the advantages of the intensive treatment, if we bear in mind that at least 25 per cent. of the patients treated by the old-fashioned methods give up treatment after the second year, in spite of our warnings, and that under these conditions the proportion of tertiaries is no longer 3 per cent., but, according to the same statistics, rises to 17 per cent.

A very important question arises at this juncture, viz., whether in the doses indicated the method is practically applicable—in other words, does it not entail drawbacks which more than compensate for its advantages as just described? Here are my figures. In my clinic about 15 per cent. of the patients cannot tolerate it, but in private practice only about 5 per cent. are unable to carry it through. The method, it may be urged, is painful; well, there may be some pain on the third day, but it is usually quite bearable and in most instances it is *nil* or merely trifling. A French physician once asserted that it was the puncture that should be painless rather than the salt injected, and it is for the practitioner to train his hand and acquire the necessary dexterity, for it must be admitted that but too frequently the injections are badly done, and that the pain as often as not is the fault of the operator.

It may be followed by abscess. Grey oil but rarely gives rise to abscess formation, but the practitioner not infrequently does for want of antiseptic precautions and suitable instruments, and I have on various occasions carried out without a hitch, to the patient's great surprise, a course of treatment which had been inaugurated by several abscesses.

During the last twelve years I have made considerably more than 10,000 injections, and I have only had four aseptic abscesses with calomel and four following grey oil. Embolism can never take place with a properly-applied method if we are careful to wait twenty or thirty seconds before making the injection in order to make sure that no blood trickles out of the needle.

As to symptoms of poisoning I have never met with anything at all serious. It is by no means rare for some discomfort to be complained of at the end of the course, but the symptoms soon clear up.

Stomatitis exists whatever method be employed, and it is very important to attend to the state of the mouth in every instance in which mercurial treatment is adopted. The dose of 0.14 centigramme of mercury for a person of average weight need not excite any alarm and it is well borne. This ought to be the average dose, for in the past we have always been giving far too little mercury to our patients.

I have shown before various Belgian societies extensive series of patients who had gone through the course of 15 or 20 injections of 0.14 cg. of mercury whose general health was excellent, who did not present any nodules in the gluteal region and whose mouths were free from the slightest trace of stomatitis. It is obvious, however, and this condition is indispensable to the success of the abortive treatment, that *the method infers the absolute functional integrity of the principal viscera*, of the liver and, more particularly, of the kidneys. In every instance the urine must be examined *before each injection*.

This method is formally contra-indicated in *the aged, the cachectic, chronic alcoholics with renal insufficiency, in arterio-sclerosis and the subjects of plumbism and gout, in the tuberculous, and in pregnant women with albuminuria*. Children bear the treatment well, the doses of course being proportionately reduced.

The abortive method, apart from the advantages which it presents in respect of the individual whose diathesis is thus sterilised, also constitutes a very advantageous method for the protection of society since, by obviating all contagious manifestation, it realises better than any other measure the prophylaxis of syphilis.

OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL.

Minor Degrees of Shock.

By Leonard Williams, M.D., M.R.C.P.,

Assistant Physician to the Hospital, Physician to the French Hospital in London.

This young man, whose age is 20, comes here complaining of the vague subjective sensations which are so commonly labelled neurotic or hysterical. He has nothing more definite to tell us than that he is "not sure of himself," "is afraid to go out," "feels all of a shake." When questioned, he says that he has no appetite and that he is sleepless. Further cross-examination elicits that these discomforts all came on suddenly three days ago, after he had had a fright. The fright was a serious one. It was caused by his elder brother, who had come home from an asylum, suddenly becoming acutely insane and escaping from home.

In the out-patient room we are rather too apt to be incredulous of the reality of the vague subjective sensations of which we hear so much from women; and the case of this young man is a good instance of the injustice we sometimes do when we dismiss these complaints as fanciful and unworthy of serious attention. It also illustrates the value of inquiring for a history in every case, however unimportant it may seem. The events which preceded this youth's neurotic attack were sufficiently alarming. They were, indeed, such as might easily upset people of the most robust organisation. His subjective sensations are evidently very real, for he is suffering from a perceptible degree of what is called shock. Physical examination does not tell us very much. He has dilated pupils, it is true, but they are equal, and react to light and accommodation. His deep reflexes are, no doubt, exaggerated, but there is no evidence of any organic disease in his nervous system. I did not expect to find any, but inasmuch as a great many organic nervous diseases show themselves by very typical "functional" manifestations, it is never safe to take for granted that physical signs are absent. More especially is it necessary to be careful in patients of this young man's age, because, of all organic nervous affections, that which is most commonly diagnosed as functional is disseminated sclerosis, and this youth is just at the age when this disease would be most likely to show the first evidence of its presence.

Now what do we mean when we speak of shock? The term shock, used surgically, conveys a very definite picture to those of us who have witnessed severe degrees of it; but used medically, and especially used socially, its significance is of the vaguest. I think, in reality—that is, pathologically—the term as thus variously applied means the same thing, only in different degrees. The essential condition in surgical shock is a generalised dilatation of the arteries. The muscular coats are no longer in the state of partial contraction which is called "tone"—the state in which they are on the *qui vive*, so to speak, to obey an order either for contraction or dilatation. They are flaccid and inert, with the result that the pressure of the fluid within the vessels becomes very much lowered, and the blood stream dangerously sluggish. It is the medulla which keeps the arteries in tone, so that if tone is absent, we must suppose the medulla to be either asleep or unduly exhausted. The medulla never sleeps, any more than the heart does, but it is often exhausted. Over-stimulation exhausts it, as in severe abdominal operations and other conditions in which the sensory nerves have been placed strongly on the rack for a long period. For the first effect of irritating a sensory nerve is to stimulate the medulla, and this produces constriction of the arteries. If the irritation of the nerve is prolonged, the medullary stimulation is also prolonged, and may be prolonged to the point of exhaustion. When this happens, the medulla is no longer able to maintain the tone of the arteries, and the vessels relax. If they relax to their fullest extent and remain so for any length of time, the blood stream becomes so sluggish that the blood does not reach the brain in sufficient quantities, and the patient dies. Fortunately, this does not often happen, but it is no uncommon thing for lesser degrees of medullary exhaustion to take place. Perhaps we ought to confine the word exhaustion to extreme degrees, and speak of the lesser degrees as medullary fatigue. Such a term does not, however, convey at all accurately what has happened in this young man's case. Here the medulla has had a "shake"; it has been subjected to a sudden violent storm, with the result that it is neither exhausted nor in reality fatigued, but its equilibrium is upset. It is still capable of reacting, but its reactions, instead of being measured, controlled, and smooth, are violent, spasmodic and jerky.

Thus it is that an estimation of this lad's blood-pressure showed a figure (120 mm. Hg.) which is normal, and when we counted his pulse in the upright and recumbent postures we failed to find the very decided increase in rate on standing which we should expect to find in a case where the medulla was really fatigued and the blood-vessels consequently in a state of undue dilatation. The medulla is always in this irritable state in hysterical or neurotic people, whose blood-pressures, therefore, present the most extraordinary vagaries. The mere fact that the patient is being examined by two or three doctors is sufficient to elevate it unduly. If we could only catch these cases when they were "themselves," uninfluenced by mental stimulation, we should find the pressure low—sometimes very low. It is then that, like Iphigenia, they deplore their fate; but let there come a stimulus, and up mounts their blood-pressure, filling them with intense ambitions to reform the world and all its contains, except, of course, themselves, who, in their own view, require no reforming. This eccentricity of blood-pressure never occurs in the condition which is so frequently confused with hysteria—namely, neurasthenia. In neurasthenia the pressure is uniformly and consistently low, and is conspicuously unresponsive to ordinary stimulation. True neurasthenia is, in point of fact, a species of "shock" in which the medulla is fatigued indeed, but not primarily, as in ordinary shock. In neurasthenia the medullary fatigue is secondary to fatigue of some of the other cerebral centres.

To confirm the suspicion that, except when subjected to the stimulus of being examined, this lad's arteries are in a state of dilation, I examined his urine, in which, as you saw, there was a distinct cloud of albumen. Dilatation of the arteries causes the blood to stagnate in the splanchnic area, and this gives rise to a passive renal congestion which, in its turn, will produce an albuminuria. Such, as I have often explained, is the train of events which is responsible for cyclical or postural albuminuria. The presence of albumen in this lad's urine is therefore strongly confirmatory of the view that, in spite of the verdict of the manometer, his arteries are unduly dilated.

The treatment of these cases is simple enough. We will take this patient into the wards, and in a few days his medulla will have recovered from its shake and will once more be working smoothly. If we are to treat him with drugs, these must be of the sedative type. Bromide of potassium and valerian will do him good by helping him to re-establish his medullary equilibrium. Tonics he does not require; they would, indeed, do him harm. More especially ought we in these cases to avoid strychnine. Strychnine acts by stimulating the medulla, so that it is obviously peculiarly ill-adapted to the treatment of a case in which the medulla is already in a state of undue irritability. If he were a rich man instead of a poor one, it would be well to send this patient to some spa or institution where he would, in practised hands, be treated by cold water baths and douches. In chronic neurotic cases, more especially, these baths do an enormous amount of good, and the place at which they are best administered is Divonne, close to the Lake of Geneva. It is as well to remember in connection with this place that it is a summer resort. I have known people sent there in mid-winter with results not altogether favourable

OPERATING THEATRES.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

Case for Diagnosis.—Suprapubic Cystotomy.—Mr. Edred Corner operated on a little girl, æt. 10, who had been admitted suffering from symptoms which pointed to disease of the bladder. The history of her illness dated from the time when she was three years of age. During this period of seven years she had been seen by many doctors, and treated as an in-patient at many hospitals throughout the Thames Valley. Briefly, Mr. Corner said her symptoms were: pain and frequency of micturition, aggravated by exercise and improving whilst lying up. On several occasions she had passed blood in her urine, but this was most frequent at the commencement of her illness, and had not occurred during the last two years; the urine, on examination, contained pus and albumen. The diagnosis made previous to her admission to Great Ormond Street was tuberculous disease of the bladder, which diagnosis was arrived at rather by a process of exclusion than on account of any positive evidence being found in its favour; no tubercle bacilli had been discovered in the urine. The child was taken to the operating theatre and examined under an anæsthetic. The bladder was first washed out, and then examined with the stone sound. The end of the sound in the bladder could be felt to impinge upon some resistance, which did not give either the sensation or the sound which a stone usually does; yet, whilst washing out the bladder, that organ had been easily distended, so that it was impossible that the resistance felt could have been due to the sound meeting the bladder wall. The bladder was again washed out, and the cystoscope passed, when the walls of the viscus were seen to be much trabeculated. A little further examination revealed the presence of a large stone free in the bladder, its surface being thickly covered with phosphatic deposit. It was impossible to gauge the exact size of the stone, because only a small portion of it could be seen at one time in the field of the cystoscope. This stone was evidently the explanation of the long history of vesical symptoms. It was thought that the stone was too large to be crushed with the lithotrite, so the bladder was again distended and a vertical incision made in the middle line just above the pubes, the anterior sheath of the rectus muscle opened, the recti abdominis muscles separated, the peritoneal pouch in front of the bladder carefully drawn upwards, and the bladder wall exposed. The bladder is, Mr. Corner pointed out, easily recognised by its colour and the tortuous veins which run on its surface more or less parallel to the incision. It is often easy to expose the bladder suprapubically in children, as in them that viscus is placed higher and more in the abdomen than it is in adults. Two guide stitches were passed through the bladder wall, which was incised between them; a finger was passed through the opening, and the large stone immediately felt. The next step in the operation was technically the most difficult of the whole proceeding; it was to grasp the right diameter of the stone in forceps and deliver the calculus from the bladder. This, Mr. Corner said, is easy when the stone is small, but may take some time when the stone is very large. The incision in the bladder was not closed, but each side was attached to the corresponding rectus muscle with a catgut stitch. Mr. Corner remarked that it is advisable to do this when the opening in the bladder is merely for temporary purposes; if the opening is to be for some time, then the bladder had better be sewn to the anterior rectus sheath or to the skin. A rubber tube was placed in the bladder through the lower part of the incision, and the catgut stitches tied together, so as to close the opening in the bladder wall round the tube. The anterior rectus sheath in the upper part of the wound was brought together with a few catgut stitches, as was also the skin. A gauze plug was placed in the lower part of the wound round the tube in the bladder. By this means, Mr. Corner said, the bladder would be drained by syphonage for three days, when the rubber tube would be taken out. Mr. Corner remarked that it seemed inconceivable that this stone could have been free in the bladder for the seven years during which the child had had vesical symptoms, and that it could have been unrecognised by so many medical men. Her pain and misery had reduced the girl, who was fair, to that thin and delicate condition so often associated with advanced tuberculosis. Her appearance, and the inability to ascertain definitely the cause of her illness, had led the diagnosis of tuberculosis of the bladder to be made; and he would suggest that this stone must have been hidden in a pouch of the bladder during the greater part of the period of her long illness; hence its presence could not be ascertained with a sound. There were three important lessons to be learnt from consideration of this case: first, the sound may be an uncertain instrument to depend upon for the diagnosis of stone in the bladder; secondly, the cystoscope may be of the greatest use in arriving at a correct diagnosis; thirdly, and from the point of view of the surgeon dealing with cases in children, a skiagraph should have been taken. The omission to take this step (almost invariably omitted by students in examinations), which must have demonstrated indisputably the presence of this huge calculus, would have saved the patient from the loss of health, education and vigour such as resulted from the last six years of her illness.

Medical Agreement.

At Pwllheli Board of Guardians meeting on November 20th, a letter was read from the six public vaccinators offering finally to settle the dispute as to the vaccination fees, and they agreed to accept 5s. per case, plus 1s. registration fee; but in the Aberdaron district, which is the remotest part of Lleyn Peninsula, a fee of 6s. was asked for, plus 1s. for registration. The board's offer was 5s. 6d. inclusive, and this they decided to adhere to. Failing acquiescence by the next meeting, the board will take steps to fill up the places.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Obstetrical and Gynæcological Section.

Meeting held Thursday, November 14th, 1907.

The President, Dr. Herbert Spencer, in the Chair.

Dr. Thomas Wilson read a paper on

PUBIOTOMY,

with notes of an illustrative case. The paper was published in our last week's impression. In the discussion that followed,

The **President** said he had no personal experience of pubiotomy or of symphysiotomy, preferring the alternative operations of induction of labour and Cæsarean section. The operation of pubiotomy had been rarely performed in Britain, but Dr. Wilson had omitted two cases operated on by Dr. Wallace, whose opinion of the operation was "not an entirely favourable one." The President thought that Dr. Wilson had not sufficiently emphasised the dangers of the operation. Baumm's two cases terminated fatally, and Robert Mann had published a case of hernia through the gap in the bone. Injuries of the bladder and vagina and thrombosis were not uncommon accompaniments of the operation, and, if not fatal, involved considerable risk. He did not think a rest of 16 days in bed was sufficient for the proper consolidation of the bone. Dr. Wilson's case occurred in a patient with a pelvis of almost normal size, and though he did not question the justifiability of the operation in this case, the special dangers of laceration of the vagina would be much greater when the pelvis was considerably contracted. Operators seemed to be divided in opinion upon the question of immediate or deferred delivery; but he thought it would be unjustifiable to submit a patient to the pains of labour after the bone had been divided unless she were kept continuously under an anæsthetic, which itself involved risk. Although the mortality of pubiotomy was not high, it probably was at least as high as induction of labour and Cæsarean section, and involved dangers which appeared to be unavoidable, and disabilities to the mother, which were not met with in the alternative operations. With regard to Pinard's views on the treatment of contracted pelvis, he would say something on another occasion. Meantime, his recollection was that Pinard had with symphysiotomy lost 12 per cent. of the mothers and children. Pinard's latest statistics, mentioned by Dr. Hubert Roberts, showed a maternal mortality in symphysiotomy of over 11 per cent., and an infantile mortality of 14 per cent. They also showed a growing faith in conservative Cæsarean section and a lessening faith in symphysiotomy.

Dr. **Macnaughton-Jones** said that, like the President, he had never had recourse to symphysiotomy. At Heidelberg Prof. v. Rosthorn had given him the details of a case in which uncontrollable and fatal hæmorrhage had occurred after pubiotomy. When he was in Freiburg in 1906, Prof. v. Krönig had performed 30 cases without a death, and had lost two children. On the other hand, Franqué, up to March, 1905, had operated 43 times, with 12 deaths and the loss of three children. Schauta, in his recent work, seemed to favour pubiotomy. The higher the head, Krönig had pointed out, the greater the danger to the bladder. The advantages over symphysiotomy seemed mainly to be the avoidance of hæmorrhage and of injury to the structures in the median line, as the clitoris and urethra; but Zweifel and others considered that the permanent effect, so far as pelvic uniformity and general gain of increase in diameter are concerned, was better in symphysiotomy than in pubiotomy.

Dr. **Griffith** referred to the great difficulty there is in discussing and comparing records of the operations of pubiotomy and symphysiotomy, owing to the different views held by different operators as to the condition which justified the operation. His own experience was confined to symphysiotomy, and he was of opinion that pubiotomy presented no real advantages, while symphysiotomy was simple, and required no special instruments. The difficulties, in his opinion, were not in the operation but in the proper choice of cases for which it was suitable. Those operators who, like the late Dr. Varnier, declined to use forceps, premature induction of labour, and any other means than symphysiotomy for every case of even slight difficulty, obtained a large number of good results both as regards mothers and infants, but this was a line of practice that does not appeal to English obstetricians. He hoped the time would come when it would be generally recognised that the treatment necessary in cases of obstruction at the brim was not to be determined by the length of the conjugate unless in extreme degree of contraction. In these cases Cæsarean section was the only method, but in all the common, slight, and moderate degrees of contraction, the length of the conjugate, while a very important factor, was never the determining factor. It was no uncommon experience to see a woman spontaneously delivered with a conjugate of about 3¼ inches, without danger to herself or her baby, while in other cases, with a conjugate half an inch longer, the difficulty and danger may be great, this depending first on the size of the child's head, a favourable position of the head in relation to the obstruction, the mouldability of the head, and the power of the uterus; and it is in the correct judgment of these difficulties that the obstetrician of experience will be able to differentiate and select those few cases to which, in his opinion, the operation should be confined.

Dr. C. **Hubert Roberts** wished to add his testimony to that of Dr. Griffith with regard to the importance of endeavouring to estimate the size of the fœtal head in contracted pelvis, and not merely depending on the actual bony measurements of the pelvis itself. As to pubiotomy and symphysiotomy, Dr. Roberts thought that possibly these operations had sprung into favour abroad largely on account of the falling birth rate. The latest statistics of Pinard, in the "Annales de Gynécologie et d'Obstetrique," for September, 1907, showed this very forcibly, and in France, at all events, it would seem that the induction of abortion and premature labour in contracted pelvis had been given up. Hence the frequent performance abroad of such operations as pubiotomy and symphysiotomy, especially the latter. Dr. Roberts had performed subcutaneous symphysiotomy once at Queen Charlotte's Hospital, with good results to mother and child. He had no experience of pubiotomy.

Dr. **Thomas Wilson**, in reply, thanked the President for referring him to Wallace's two additional cases, which brought the total number of pubiotomies performed in this country to ten. Where, after dividing the bone, the labour is left to the natural efforts, it does not appear to be necessary to keep the patient anæsthetised. The pain following operation in Dr. Wilson's case was moderate, and this appears to be the rule. Time must show whether symphysiotomy or pubiotomy is the better operation. The latter appears to possess over the former the advantages of being less liable to cause severe bleeding, of endangering the bladder to a less, and the urethra to a much less, degree. It is remarkable that no discussion on pubiotomy had previously taken place in London, and that no one in this city appears to have put the operation to a practical test.

The following specimens were shown:—

Dr. **Herbert Spencer**: Squamous carcinoma of the cervix in a patient, æt. 26. High amputation with cautery. Patient shows no recurrence six and a-half years after.

Mr. **Alban Doran**: Ovarian dermoid retained two years in the pelvis after obstructing labour.

Dr. **Fairbairn**: Fatal rupture of an early tubal pregnancy.

Dr. **Macnaughton-Jones**: An improved demonstration pelvis.

Dr. **Thomas Wilson**: Unilateral hæmatometra recently acquired by operation.

Dr. C. E. **Parslow**: Pregnant uterus with fibroid, the latter in a state of red degeneration.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, November 8th, 1907.

The President, J. M. Redmond, in the Chair.

FUNCTIONAL SPASTIC PARAPLEGIA.

Dr. **Craig** exhibited a coachman, æt. twenty-three, who had been admitted to the Meath Hospital in March, 1906, complaining of pain, coldness, and a dead feeling in his left leg. He attributed his condition to a wetting, received a year before, when he wore a broken boot. A sensation of "pins and needles" in his left foot and leg followed. Subsequently cold sweats occurred in the leg accompanied by pain which passed up his side into his left arm. Later the pain again attacked and settled in the calf of his left leg, while from the hip down the limb was cold and numb. Tremors then appeared in the leg, so that on attempting to walk he staggered like a drunken man; spasm of the muscles in the leg and extension of the tremors to the other leg and to the arms followed. Examination revealed increased knee jerks, some attempt at ankle clonus in the left leg, slight nystagmoid movements of the eyeballs, no slurring of speech, rhythmical tremors appear in the limbs on using them. He was thought to have disseminated sclerosis, and left hospital in about six weeks without any change in his condition. He weighed 10st. 2lbs. on leaving hospital in April, 1906. The patient came into hospital again about a month ago, this time under Dr. Craig's care. He now attributes the onset of his illness to his having slept on a mattress on a stable floor while nursing a sick horse. He says his legs and left arm are weak, and that he has shooting pains which run up his legs, along his sides, across his chest and down again. In the left arm he has shooting pains which escape by the tips of his fingers. He is now only 8st. 7lbs., and appears to be wasted, but the wasting is quite general. He is unable to stand with his eyes closed, and staggers considerably when walking, knee jerks are increased, there is no ankle clonus, but on the left side a few spasms of rectus clonus are elicited which give him pain. There is a flexor plantar reflex. Hyperæsthesia to touch, pain and heat is universal. He has a fairly coarse tremor, seen well in his arm when he places a forefinger on the tip of his nose. He has very slight nystagmoid twitches on extreme lateral movement of the eyeballs. Sir Henry Swanzy reported that otherwise his eyes are perfectly normal in every respect. There is no trouble connected with either bladder or rectum. During his previous stay in hospital the diagnosis of disseminated sclerosis was undoubtedly made on the weakness of the legs with increased knee jerks, the tremor and the nystagmoid twitchings. The case is, however, a functional one. The pain and numbness complained of early in 1905 were probably due to sciatica. When he came into hospital on the present occasion ataxia was the most prominent feature of the case—to-night he is free from ataxia. The knee jerks are also less responsive, and even the tremor is not so marked. This morning it was quite absent from both arms. When now examined he exhibits to-night, for the first time, a spurious clonus in the right leg. It is due to spasm of the thigh muscles; the ankle is quite unmoved. On rubbing his forehead with a forefinger or on gently pulling the hairs of his legs he complains of pain. The hyperæsthesia is quite general. The points, however, upon which Dr. Craig most confidently relied in pronouncing against the existence of an organic lesion in the brain and cord are—(1) absence of ocular signs, such as optic nerve atrophy, contraction of the field of vision, limitation of muscular movements; (2) absence of any involvement of the bladder and rectum; (3) absence of true ankle clonus and toe-extension phenomenon. Hyperæsthesia is less common in purely hysterical cases than anæsthesia, but taking this symptom of general hyperæsthesia with the loss of flesh and the general aspect of the patient, Dr. Craig regarded his condition as neurasthenic rather than hysterical—in fact the case presents that alluring symptom group which is so frequently found in people who have received an injury for which compensation is expected. The patient was exhibited to-night in order to draw attention to the importance of making an accurate diagnosis in cases exhibiting nervous disturbances, because of the important differences in the prognosis between an hysterical or functional paraplegia like the present one and a case of, say, disseminated sclerosis. The man has been taking valerianates for the past ten days. Dr. Craig had told the patient that he will get well, and already he was much impressed with the improvement that has taken place, and which he confidently expects will be continued.

Sir **Christopher Nixon** said it would be difficult to conceive that a case which presented such varied disturbances from the normal could be regarded as simply functional in character. He thought the term functional paraplegia was open to grave objection. It did not explain in any way the multitude of symptoms in the case. At first it undoubtedly showed the ordinary symptoms of disseminated sclerosis. There was more about the man than simple functional disturbance; and, while he had the greatest respect for Dr. Craig's acumen in diagnosis, he claimed that there was always room for latitude in nervous diseases, and expressed the opinion that the case was one of disseminated sclerosis undergoing a period of remission.

Dr. **Drury** said he had seen the case before, and could bear out Dr. Craig's statement that the symptoms were different then from ten days previously. He did not think, however, that they could altogether depend on the absence of bladder symptoms as necessary early in diagnosis. In nearly all chronic nervous cases very marked functional manifestations appeared. He did not think that any of them could either condemn the patient as being a case of organic disease or buoy him up with the idea that it was merely functional unless they had gone into the case with greater fulness, and they might depend on the diagnosis of Dr. Craig, who had studied the case.

Dr. **Travers Smith** said that if he had to give a working opinion of the case he would give the same as Dr. Craig, and he believed the patient would get well. By that he would imply the loss of function of some portion of the nervous apparatus, without any discoverable anatomical change to account for it. He did not think they need be afraid of diagnosing functional disturbance while still keeping their minds open to the possibility of its being only preliminary to permanent disturbance. He thought that the very rapidity of the changes that had occurred in the case, as well as present symptoms, were all in favour of functional disease.

Dr. **Walter Smith** said that in their present hazy state of knowledge of many aspects of nervous disease, he would hesitate to pronounce a definite opinion as to the exact state of the case, but he shared Sir Christopher Nixon's objections to the use of the word functional, which, he hoped, before long would vanish from medical nomenclature. If a term must be used, he would prefer the word hysterical, which connoted a state of things better than functional. Stress had been laid on the point that if the patient got well, the diagnosis of functional disease would thereby be substantiated, which was as much as saying that if the patient had organic disease he could not get well, and therefore recovery would make a different diagnosis—a line of argument which was quite unwarrantable. The recent demonstration that the nerve-supply of the bladder and rectum was not derived from the lumbar region should modify their consideration of the matter, and he would hesitate to accept Dr. Craig's diagnosis as absolutely correct.

Dr. **Moorhead** said he had seen the case previously, and had disagreed with Dr. Craig's diagnosis, but he had since come to think that the disease was functional.

Dr. **Purser** discussed the site of functional degradation in this case.

Dr. **Craig**, in reply, said he did not regard the absence of bladder symptoms as of vital importance, but in nearly every case of disseminated sclerosis with pronounced symptoms bladder symptoms were present. He only dwelt on the absence of such symptoms because it was in combination with the absence of ocular phenomena and ankle clonus.

EXHIBITS.

Dr. **Winter** showed a case of amyotrophic lateral sclerosis. The patient was a coachman, æt. thirty-eight, who, about six months before he first saw him, noticed that he was wasting between the thumb and first finger of the right hand; he did not then notice any weakness. Since that time atrophy of the muscles has proceeded rather rapidly, the muscles chiefly involved being those of the right hand, the extensor of the right wrist, and the deltoid and triceps, but there is also some wasting of the muscles of the left hand. A very well-marked feature of the case was the fibrillary contraction of the muscles, which was present in the muscles of both arms, and also both pectorals and the scapular muscles. There were no bulbar symptoms. In addition to his muscular atrophy the patient showed exaggerated knee jerks and sometimes ankle clonus, the reflexes in his arms being also exaggerated, but beyond the facts elicited by examination the patient showed no spastic symptoms, and although at first sight the case looked like one of progressive muscular atrophy Dr. Winter thought that the name under which he had exhibited the case gave a better idea of the conditions that were found, and, in his opinion, the case tended to confirm the view that the two conditions were identical.

Dr. **Travers Smith** showed cases of (1) progressive muscular dystrophy, (2) paroxysmal tachycardia, (3) a man who exhibited symptoms of a combination of locomotor ataxia and multiple neuritis.

These were discussed by Drs. **Little**, **Craig**, and **Moorhead**.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held Friday, November 15th, 1907,

Dr. **George Carpenter** in the chair.

Dr. **G. H. Lock** read a paper on a case of

RHEUMATIC HYPERPYREXIA

in a child of six, who a year previously had had an attack of chorea. On September 10th, 1907, she had left lobar pneumonia, which terminated by crisis on the fifth day; two days after the crisis the choreiform movements returned.

On September 20th there was pain in the left hip, and the temperature rose to 100 deg. F. Subsequently other joints became involved, and the case was a typical one of acute rheumatism with chorea. On the third day the temperature rose to 107 deg. F. In spite of treatment by ice pack and graduated bath, death occurred on the fifth day, the temperature just before death being 110 deg. F. The severe choreic movements ceased only with death.

Dr. **Eldon Pratt** read the notes of a case of (1) fractured lower jaw in a child of four. The child had been kicked by a horse, and the fracture was vertically through the symphysis. It was treated by a dental splint. Union was firm at the end of fifteen days, and a perfect result was obtained, there being complete absence of any deformity.

(2) Notes on a case of vaccinia. The patient was a baby who was vaccinated when six days old in four places on the left arm. Six days later all four places had taken well; ten days later there was extensive ulceration over the arm, measuring 3¾ inches by 4¼ inches, the surrounding skin was much inflamed, and there were pocks of auto-inoculation near the left axilla and over the right ribs. The whole of the body, face, and limbs was covered with a diffuse papular rash. The condition rapidly subsided under boracic fomentations.

Dr. **George Carpenter** showed a boy of 11, with a "Tuberculous Tumour of the Pons," verified by Calmette's ophthalmo-reaction. Subjective symptoms commenced in August; optic neuritis and ophthalmoplegia externa appeared the end of September. He was now leading a fatuous existence, and had continuous incontinence of urine and fæces. He could answer questions rationally, and called out if he wanted anything. Headache was now rarely complained of, sickness had disappeared, the knee jerks were absent, he lay curled up in bed, and although blind from choked discs was contented.

Dr. **Carpenter** was not in favour of trephining for the relief of optic neuritis; he thougnt the drawback of a hernia cerebri, the improbability of ameliorating the local condition, and the possibility of bringing the child back to even a temporary recognition of its unhappy state, contra-indicated any surgical interference.

Dr. **Poynton** showed a case of œdema persisting since birth. Child æt. two years, male. Swelling of the feet had been noticed since birth, varying in amount; eyelids had been swollen in the mornings; there was well marked swelling on the dorsum of each foot, with slight pitting on hard pressure. Urine normal quantity, faint trace of albumen, and a few degenerative cells with scattered leucocytes; no casts or crystals. He thought that there was some renal fault of congenital origin.

Dr. **G. A. Sutherland** showed a female child of seven months. The feet had been swollen since birth, the sole of each foot being tense and hard, while the dorsum was soft and pitted on pressure. Marked blueness of the foot followed exposure to cold. The child had suffered for some weeks from lichen urticatus, with very large wheals on the head. There was no evidence of renal or cardiac disease. The hands were not œdematous, but became blue on exposure to cold.

Mr. **Russell Howard** showed a case of precocious development of the obese type in a girl. He could find no evidence of any disease of the ductless glands, or the accessory genital organs.

Dr. **Porter Parkinson** showed a case of (1) facial paralysis in a girl, æt. 3½, with some weakness of the leg, apparently due to encephalitis. (2) A case of lymphadenoma affecting the cervical glands in a boy, æt. six.

Mr. **R. Warren** showed a case of congenital dislocation of the hip joint in a girl of 5 years. Skiagrams showed that the femur had a very small neck and no head.

Mr. **Hugh Lett** showed a case of acute arthritis of the hip joint in a boy of 11; treated by irrigation and drainage. The patient had recovered with perfect movement in the joint.

Dr. **Clutterbuck** showed a case of intention tremor in a child of 5½ years. Labour was tedious, and completed with instruments. No history or evidence of syphilis. The child never had convulsions. She is rather backward mentally, and did not walk until she was three years old. There was coarse intention tremor of the hands, and marked inco-ordination and spasticity of the lower limbs. The knee-jerks were increased, and Babinski's sign was present. No changes in the fundi.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held at Sheffield, November 15th, 1907.

The President, Dr. **E. O. Croft** (Leeds), in the Chair.

Mr. **R. Favell** (Sheffield) exhibited two specimens of "Fibro-myoma Uteri," one undergoing calcareous, the other cystic degeneration. (2) An ovarian cyst, in which axial rotation of the pedicle had occurred. (3) Syphilitic hypertrophic enlargement of the labia majora in a patient, æt. 28, who had one child nine years ago. There had been no abortions. She gave a history of a lump in the external genitals for the last eight years. Soon after her confinement, a year previously, she had noticed some small hard lumps about the anus which never quite disappeared. Five years ago one of these tumours was the size of a hen's egg, and within the last six months others had appeared. The largest growth, the size of a small cocoanut, was in the left labium majus. Both labia were excised, and microscopic examination showed a loosely-woven fibrous tissue structure, with inflammatory reaction, especially around the vessels.

Mr. **Archibald Cuff** (Sheffield) showed calculi removed per vaginam from the left ureter of a patient who suffered from symptoms of stone in the kidney. A radiograph located them 2 inches above the entrance of the ureter into the bladder.

Dr. **Miles H. Phillips** (Sheffield) exhibited the uterus containing a submucous fibroid undergoing sarcomatous change. It was removed by abdominal section from a nulliparous patient, æt. 50, in whom menorrhagia had been present for nine years. There had been inter-menstrual bleeding and an offensive purulent discharge for 14 months. On admission the temperature was 101, and small sloughs were detected in the vaginal discharge. The cervix uteri was patulous, and the uterus was the size of a four-months' pregnancy. Exploration of its cavity revealed a friable growth which microscopically proved to be sarcomatous. The cervix was therefore stitched, and removal of the uterus and appendages carried out by abdominal section. Five weeks after the operation the patient died suddenly from pulmonary embolism, and the autopsy revealed septic thrombi in the internal iliac veins and an embolus in a branch of the right pulmonary artery; there was no peritonitis. The microscopic sections demonstrated a mixed-cell sarcoma originating from the muscular fibres, submucous fibromyoma, and invading the uterine wall.

Dr. **Percival E. Barber** (Sheffield) mentioned the case of a woman, æt. 34, who had had one child three years ago. Two weeks after an abortion bleeding began, and was accompanied by a febrile condition. The uterus was enlarged and the cervix patulous. Suspecting chorion-epithelioma, a scraping removed by the blunt curette was examined microscopically, but did not confirm suspicion. As the patient was becoming progressively worse, abdominal section was performed, but her condition did not justify an attempt at the removal of the uterus being carried out. Recovery, however, gradually took place, and the patient became perfectly well.

Dr. **W. E. Fothergill** (Manchester) mentioned two cases illustrating the value of Schuchardt's paravaginal incision. In the case of a single woman, æt. 38, with a large submucous fibroid, the uterus extending to the umbilicus, abdominal section was contraindicated on account of an extremely offensive discharge in a debilitated patient. The removal of the tumour was rendered possible per vaginam by an incision into the left ischio-rectal fossa, and extending backwards to a point half an inch behind the anus. In the second instance, also in a single woman, with a very narrow vagina, hysterectomy for a myomatous uterus was performed after a preliminary incision.

Mr. **R. Favell** also reported four cases of ectopic gestation. *Case* I.—A woman, æt. 27, who had one child 12 months ago; had menstruated regularly 3/28 days. Her last period began a month ago, and continued for a week. It was followed by a severe peritoneal crisis. On admission there was marked tenderness in the right flank, and a soft swelling could be felt behind the uterus. Abdominal section performed forthwith revealed free blood in the peritoneal cavity, and clots in the pouch of Douglas. One inch from the uterine attachment of the right Fallopian tube there was a swelling the size of a filbert nut, on the posterior aspect of which a rent had occurred. The tube was removed, and recovery was uninterrupted. *Case* 2 was of a full-term ectopic gestation, in a woman, æt. 30, 10 years married, with one child nine years old. Menstruation was in abeyance from November, 1906, until July, 1907, when she had a red vaginal discharge for a week. At this time she felt movements in the abdomen. She had become progressively stouter, and thought herself pregnant, but as labour did not come on, she sought advice a fortnight since. The abdominal tumour resembled the full-term uterus, but no fœtal parts could be felt, and no heart-sounds or souffle heard. At the upper limit of the tumour there was something like a softened fœtal head. Bimanually the cervix was hard and closed, and the uterus lay between the tumour and the symphysis pubis. The sound passed 5 inches. Abdominal section showed the gestation sac to be adherent to the parietes and omentum, and to be intimately connected with the left appendage. The uterus lay in front and to the right. The sac and its contents were removed intact, and although there was considerable shock following the operation, the patient was making a good recovery. The specimen was being investigated. In the other two cases there was disease of the opposite appendage, which was also removed, and in one case the uterus was also removed, as the sac was intimately adherent to it.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 24th, 1907.

Treatment of Gastric Ulcer

At the ninth session of the Congrès de Médecine held last month in Paris, three questions were treated: Hemophilia, ulcer of the stomach, and exophthalmic goitre. M. Linossier read a paper on the treatment of gastric ulcer, of which the following is a summary:—

Dietetic Treatment.—Theoretically, absolute suppression of all gastric activity, complete rest of the organ until complete cicatrisation of the ulcer would be the ideal treatment, but in practice, the danger of inanition is an obstacle to this desideratum.

Was it not possible to introduce, otherwise than by the mouth, alimentary substances into the organism so as to realise rest of the stomach without the inconvenience and dangers of inanition? To meet this end four different methods have been tried; subcutaneous, peritoneal, jejunal, rectal.

As to the value of nutritive enemas, it is impossible to arrive at a formula applicable to every case. In certain subjects, absorption is almost nil, while in others, these enemas seem to almost suffice for the needs of the organism. However, the psychic action of this treatment must not be lost sight of; the patient is convinced he is nourished and for that reason supports inanition.

Where the suppression of all liquid or solid food, although momentarily, is considered impracticable, the diet allowed should fulfil four conditions; not to provoke any irritation of the gastric walls, that is to say, the food should be liquid or slightly thickened, neither too hot nor too cold; to sojourn as little time as possible in the stomach; to stimulate as little as possible the gastric secretion; to protect, if possible, the ulcer from the digestive action of the gastric juice.

Medical Treatment.—Absolute rest in bed and the ice bag to the epigastrium. Although its action on the hematemesis is doubtful, it is a good means of keeping the patient quiet. After a few days, the ice can be replaced by a simple warm compress, protected against evaporation and refrigeration by means of oil silk or some other impermeable tissue. The patient must be well covered in bed, and hot bottles placed to his feet, as any lowering of his temperature is very prejudicial.

If the subject is sufficiently vigorous, total suppression of solids or liquids by the mouth might be prescribed, and towards the second or third day subcutaneous injections of artificial serum might be given.

Nutritive enemas will be prescribed as soon as the patient can support them. Each morning an evacuating enema will be given first and after its operation, a nutritive enema, which can be repeated twice during the day.

Egg, one.
Dextrin, 2 dr.
Phosphate of soda, 15 gr.
Bicarb. of soda, 15 gr.
Laudanum, 6 drops.
Water, 10 oz.

If these enemas are well tolerated, they might be increased in nutritive value.

Eggs, 2 or 3.
Dextrin, 4 dr.
Bicarb. of soda, 15 gr.
Beef tea (without salt), 10 oz.

If well tolerated, this treatment might be continued a week, when a little sweetened water may be given by the mouth, and on the following day milk. The quantity of milk given the first day should not exceed ten ounces, when it may be gradually increased to a quart and a half. If the patient complains of burning in the stomach (due to a too free secretion of H.Cl.), the hyper-acidity might be corrected by a little bicarbonate of soda, but in such cases only. While undergoing this first period of nutritive régime, the stomach of the patient should be carefully examined by percussion and palpation so as to ascertain that it has not become distended for want of tone, and that the evacuation of the contents is not abnormally prolonged. In such a case the quantity of milk must be diminished, but its nutritive qualities may be increased by the addition of milk powder, lactose, cream, rice, tapioca, or casein. Where pain persists in spite of this more nutritious régime, bicarbonate of soda or subnitrate of bismuth might be prescribed in large doses. If no relief comes from this treatment, the question of operating might suggest itself (gastro-enterostomy).

Constipation is best treated by enemas of olive oil, and anemia by subcutaneous injections of cacodylate of soda.

Such is the treatment of a typical case of gastric ulcer, and if properly conducted, the symptoms disappear, but frequently the cure is only apparent and momentary, and the patient is always exposed to a relapse.

Treatment of Hæmoptysis.

The first thing to be done and before all other treatment is to inject 4 drachms of a solution of gelatine into the cellular tissue of the abdominal wall.

Gelatine, 2 dr.
Chloride of sodium, 1 dr.
Water, 1 pint.

The solution should be sterilised. The injection should be repeated each day or twice a day if necessary.

Internally:—

Ergotine (Bonjean), 1 dr.
Gallic acid, 10 gr.
Syrup of turpentine, 1 oz.
Water, 4 oz.

Chloride of calcium, 1 dr.
Ext. of opium, 1½ gr.
Syrup of peppermint, 1 oz.
Water, 4 oz.

A tablespoonful of these two mixtures to be given alternately every hour.

If the hæmoptysis does not yield to this treatment, an acid mixture might be tried.

Aromatic sulphuric acid, 4 dr.
Water, 1 quart.
A wineglassful every two hours.

Or,

Digitalis powder, } a a gr.
Hippo. powder, }
For one pill.

Five to six daily, until nausea sets in.

GERMANY.

Berlin, Nov. 24th, 1907.

At the Verein für Innere Medizin, Hr. E. Klebs discussed the subject of

Immunisation in Tuberculosis.

He said that in civilised lands the majority of the population had suffered at one time or other from tuberculosis, the traces of which were recognisable. Naegele's assumption that 90 per cent. had thus suffered was not far wrong. From the speaker's own investigations he would say that the percentage of people who had been attacked by the disease and had recovered more or less of themselves was 65. These recovered by self-immunisation, for self-recovery and immunisation were the same thing. But this self-healing was, in consequence of self-infection, very frail. The phthisical patient who expectorated tubercle bacilli up to his old age, and was therefore a danger to those around him, was himself immune, until he succumbed to a relapse. If these senile tuberculous patients had no cavities, they died of repeated catarrhs, which were not recognised as tuberculous. Such cases were extraordinarily frequent. Even in middle life such conditions were by no means unknown.

It might, perhaps, be objected that such a partial immunisation did not deserve its name; but it happened everywhere, and in all diseases; there was everywhere a partial and relative immunity. The histories of small-pox, and the plague, of cholera and diphtheria showed this.

Now arose the question that could only be settled experimentally: How did immunity arise in tuberculosis? It was undeniable that self-healing took place in a few cases, and our endeavour must be to bring about this result at pleasure. These experiments in immunisation could be carried out in two directions, either by procuring mitigated bacilli, as was done by Pasteur, and after him by Chauveau in the seventies, or by searching for immune bodies in tubercle cultures.

The speaker had become acquainted with two facts that struck out a more accurate way of reaching immunity. The first was that in the recovery of guinea-pigs from tuberculosis the active principle lay in the substances passing over in the glycerine extract of tubercle bacilli. He further found in his experiments with injection of tubercle bacilli, where the injections were successful, the wandering cell became active, and led the tubercle bacilli to the nearest lymph glands. In the blood, on the other hand, the tubercle bacilli were mostly quickly destroyed. In inhalation experiments he found that when tubercle bacilli reached the lungs in small quantity, the lungs soon got free of them, under normal circumstances, as the wandering cells took up the tubercle bacilli and without exception carried them to the bronchial glands. The tubercle "sozine" prepared from the glycerine extract of tubercle bacilli favoured this action, and might lead to recovery. After showing some tables relating to his experiments and preparations, the speaker said that we here saw a genetic connection between scrofula and tubercle. The scrofulous new growth was in the first place the result of hyperleucocytosis caused by tubercle bacilli products; the dead tubercle bacilli were found in large-celled lymphocytes in the scrofulous glands. This hyperleucocytosis was also demonstrable in the blood. Whilst the normal for guinea-pigs was 10,000 leucocytes, with 5·6 to 5·7 millions of erythrocytes, the number mounted in animals that had been treated with tubercle-sozine to 18,000 to 20,000.

Whence these tuberculophile wandering cells came was not clear. They were mostly thought to come from bone marrow, but his cases rather pointed to the spleen. It was a fact that these disturbances that were not wanting in human tuberculosis always began with swelling of the spleen, and belonged to the most typical form of pseudo- or true leucæmia. At any rate, they always led to splenomegaly. As a second organ the liver became diseased, so that properly all these cases were examples of the so-called Banti's disease—splenomegaly with cirrhosis of the liver. Death took place when the like process finally took place in the lungs. The speaker would trace back the whole group of lymphomata and lymphosarcomata to such latent tuberculosis. In these cases these tuberculophile wandering cells did not die, but lived on independently in the organs into which they had wandered. This new growth, therefore, resting on a pathological basis, was originally a natural process of cure which only did harm when it was in excess. Lymphomatosis and leucæmia stood near together genetically, and probably to be ranked with them was Hirschfeld's erythræmia with splenomegaly. Naturally other things might set up a similar process—for example, feeding with carcinoma.

This specific artificially induced leucocytosis had still another aim—it always reduced the temperature, for the reason, according to the speaker's opinion, that the tubercle bacilli that led to fever through their dissemination in the blood were conducted to the lymph glands and there taken up.

Investigations were in progress for the purpose of showing how far this inoculation would remove a fresh infection, or carry an existing one to recovery. Of course, the usual bactericide substances would still be employed in all cases of serious tuberculous infection.

AUSTRIA.

Vienna, Nov. 24th, 1907.

Multiple Sclerosis and Urinary Trouble.

Hochwart presented a patient, æt. 16, to the "Gesellschaft für Innere Medicin" with a persistent desire to micturate, evidently due to a nervous origin. The bulbar shaking in the extremities and eyes was unusually slight. The urine was normal. A few months before this examination the patient was troubled with retention, followed by a dribbling, uncomfortable condition. Then commenced nystagmus, increased patellar tendon reflex, more sensitive in the left than the right, slight ataxia in the left extremity, and hyper-hemi-algesia in the left side. All the phenomena of multiple sclerosis were present.

Optic Aphasia.

Stejskal next exhibited a case from the Second Medical Clinic which he diagnosed as optic aphasia after a severe attack of meningitis. When received into hospital the patient was stupid or benumbed mentally, neck stiff, pupillary reaction in left eye quite gone, but the right responded slightly. The abdomen was distended; taches cérébrales and Kernig's symptom—*i.e.*, loss of contraction in the lower extremities by passive movement. There was also bradycardia = 64, with elevated temperature, confirming the symptoms of meningitis. Later bilateral neuritis optica set in, with right hemi-anopsia, right facial paresis, with a slight deviation of the tongue towards the right when put out of the mouth. Three weeks later the patient improved in every one of the symptoms, but a pronounced sensorial aphasia set in, which also improved after a time. Repeated aspirations in the lumbar region were performed, giving on every occasion a hæmorrhagic fluid rich in leucocytes and rods with capsules which gave a negative result with the Gram method. Prof. Ghon said these bacilli belonged to the capsule group, and in shape resembled Friedländer's bacilli. Many cultivations in opposition to expectoration proved it invulnerable to this mode of treatment, as the capsuled bacilli are usually easily cultivated.

Hypoplasia of the Aortic System.

Hans Politzer brought in a case from the Second Clinic with a defective aortic system and hypertrophy, with dilatation of the heart. The apex beat was in the fifth intercostal space two finger-breadths outside the mammillary line, with every sign of hypertrophy and dilatation. Auscultation gave a systolic murmur loudest over the pulmonalis, where a second pulmonary sound was heard. The heart's rhythm was regular, pulse 88 to 92, no pulsation in the cervical veins, but the carotid was small, with a very weak pulse. There was no sub-clavian or jugular pulse even when the diaphragm was highly elevated. The radial and crural arteries were very small, while no pulsation could be found in the dorsalis pedis.

From this he concluded there was hypoplasia of the aortic system, with hypertrophy and dilatation of the cardiac. The patient was pale, with 6.5 millions of erythrocytes and 16.6 per cent. of hæmoglobin.

Cirrhose Bronzee.

Falta exhibited a case of cirrhosis from the First Clinic. The case was received into hospital with alcoholic polyneuritis, enlargement of liver and spleen, ascites, and a mulatto bronzing of the skin over the whole body. When the neuritis subsided the bronzing of the skin became much less, showing a direct connection with the neuritis.

Cirrhose bronzée, cirrhose hypertrophique pigmentaire, or cirrhose avec Mélanodermie, are all characteristic of alcoholic excess, which seems to produce a hæmo-chromatic substance in the large organs of the body, lymphatic glands, skin, lungs, bone, marrow, etc. This condition seems to have a close affinity to the diabète bronzé, Cachexie bronzée, dans le diabète sucré, and may be the origin of the hæmo-chromatosis. This substance is found as fine granules in the basal cells of the Malpighian layer.

Cardiac Insufficiency.

Eppinger gave a description of his experiments on animals to test the efficacy of under-feeding or hungering would have on a hypertrophic heart. His results clearly show that after five days the animal is unable to bear insufficiency or the sinking blood pressure, but if intravenous injections of dextrose, levulose and glycogen be given, the pressure rises and the animal is quickly restored.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Women Graduates and the University Franchise.—A further stage in the action brought by some of the women graduates against the Universities of Edinburgh and St. Andrews was reached on Saturday, the 16th, when the judgment of the Lord Ordinary was upheld by the Extra Division of the Court of Session. The action was raised in order to compel the University to send voting papers to the female graduates, and for declarator that women are entitled to vote at the election of a member of Parliament for the Universities. The decision of the Lord Ordinary was against the women graduates, and against this decision they re-claimed. Lord Maclaren, in giving the judgment, said that it was a principle of the unwritten Constitutional law of the country that men only were entitled to vote. Ambiguous expressions in Acts of Parliament must be construed in the light of Constitutional principles. If it was intended to subvert a Constitutional principle, it must be done by the Act in the plainest language. At the time the Act was framed it was not necessary expressly to exclude women, because women could not then be legally on the register. The argument was that a franchise originally conferred on graduates who were necessarily men had been extended to women, not by a direct enactment, but by the indirect effect of an Act of Parliament which was concerned only with academic functions, and in the interests of the higher education of women authorised their admission to a degree. It was difficult to conceive that the Legislature should have devolved the power of conferring the franchise, a power which it had always kept in its own hands. The Lord Ordinary's judgment was therefore affirmed, and the reclaiming note refused.

Glasgow Medical Officer and the Plague.—Dr. Chalmers states that towards the middle of October a case of plague was admitted to hospital. The boy is now free from infection, and is progressing favourably. When this case occurred it was also established that a death in August last had been due to a like cause. Both were removed from the same district of the city. According to Article 7 of the Paris Convention, the occurrence of such an isolated case does not constitute an infected area, and the measures prescribed by the Convention for infectious areas are not put into operation. Article 9 provides that any area which may have been declared infected ceases to be so five days after the death or isolation of the last case in hospital.

Tuberculosis and the Glasgow Milk Supply.—Dr. Chalmers states that in consequence of the detection of tubercle bacilli in samples of milk taken at a railway station, the public authorities of the district whence the milk came arranged to inspect all the dairy animals. This led to the discovery of two cows with tuberculous udders. As a further result of the inquiry, Dr. Buchanan reports two additional infected samples of cream from another county, and inquiry at the farms there has revealed the existence of cows with udder disease. In 77 samples of cream, three have been found capable of transmitting tuberculosis. The question cannot remain long unsettled as to the course a consuming authority may adopt when tuberculous milk is on sale within its area, along with milk produced at its own byres under conditions which render tuberculosis improbable. It might be desirable to secure Parliamentary power to prohibit the sale within their own boundary of milk from districts where repeated evidence of tuberculosis among milch cows had been obtained.

WOODILEE ASYLUM: ANNUAL REPORT.—During the year there were 1,271 patients under treatment; 177 males and 159 females were admitted, and 75 men and 80 women were discharged. The deaths numbered 123 —males 58, women 65. The rise in the admission rate was 71 as compared with last year; this is due to the reception of imbeciles from the Larbert and other institutions, and to the admission of senile cases. On this account the recovery rate is also unusually low—27.79 per cent. as compared with 37.9 in the preceding year. A system of electric baths has been installed in the men's asylum.

BELFAST.

THE IRISH UNIVERSITY PROBLEM.—Mr. Birrell in a speech delivered at Belfast during the past week added a little to our knowledge of his proposed solution of the Irish University question. In the first place he told his audience that all the surmises which had recently appeared in the newspapers was "all unauthorised and almost wholly false." He then added that "we cannot expect to attain what we want without a considerable amount of unanimity," and he rejoiced to say he was receiving a "considerable amount of support even from quarters where he did not expect it." He told his audience that "the question was a very difficult one," and that rightly or wrongly he believed he had "the opinion of the best people in Ireland, irrespective of party, behind him." He then added: "We know that seats of learning in these days must be entirely unsectarian. They must be free, they must be on their emoluments, in their fellowships, in everything pertaining to them free and open to all the world, irrespective of religious opinion." The Bryce scheme is dead. A *bonâ fide* Catholic University scheme is apparently equally dead—though of that there was never any doubt, and everything points towards the fulfilment of the recommendations of the Robertson Commission, as we have already pointed out in our last issue. Whether this scheme is to be modified by the establishment of a University in Belfast will probably not be definitely known for some time, but in view of Mr. Birrell's statement regarding the accuracy of newspapers, a Belfast independent University does not seem to be likely. But for that statement, there are many indications that such a scheme is in the air.

THE REGISTRAR-GENERAL AND REGISTRATION DISTRICTS.—At a meeting of the Lisburn Board of Guardians last week an interesting discussion took place on the reading of a letter from the Registrar-General, refusing to constitute the Purdysburn Infectious Diseases Hospital into a separate registration district, as he had been requested to do. He replied that in no case, so far as he was aware, had any public institution in the United Kingdom been made a separate district for registration purposes, but, as Dr. Orr pointed out, there is probably no other instance in the United Kingdom of a large city "dumping the physical and mental wreckage of the city" into an unoffending country district. It must be remembered that not only is the Infectious Diseases Hospital for Belfast situated at Purdysburn, but also the District Asylum. It certainly seems rather hard on the registrar for the district that all the extra registration work which this involves should fall upon his shoulders; work which really belongs to the City of Belfast, and not to the Lurgan Union.

PROPOSED INEBRIATE HOME FOR THE NORTH OF IRELAND.—An informal meeting was held last week in the Medical Institute, Belfast, to discuss the proposal to open an inebriate reformatory somewhere in the North, the suggested site being the disused County Gaol at Downpatrick. The meeting was convened by Dr. Norman Barnett, the honorary secretary of the local branch of the British Medical Temperance Association, and was presided over by Dr. Calwell, the president of the same body, but the attendance was not limited to medical men, a number of clergymen of all denominations and several laymen being present. There is no such reformatory in Ulster, or indeed north of Dublin, and the meeting was generally agreed that it was quite time to start one, on the broadest possible foundations, and a committee was formed with this object in view.

HEALTH OF SCHOOL CHILDREN.—At a meeting of the Public Health Committee held last week a report on the International Congress of School Hygiene was presented by Dr. Henry O'Neill and another member, and a series of recommendations were made. These, if adopted, would revolutionise education in the city, for they advise the Corporation to take over the control of secular education in both primary and secondary schools, providing and maintaining new primary schools where necessary, and to appoint a special medical officer, under the Medical Officer of Health, to supervise school hygiene in the city. Dr. O'Neill is a barrister as well as a medical man, so he has presumably considered the legal aspects of his recommendations, but they strike one as fairly courageous and sweeping!

TUBERCULOSIS.—Belfast is revelling in an orgy of popular medicine at present, the Tuberculosis Exhibition being in full swing. It was opened on Friday, 22nd, with an address by Sir Douglas Powell, who created a little breeze in medical circles by expressing his disapproval of compulsory notification to which the Ulster Medical Society, like most other medical bodies in Ireland, is committed. It is said that we may comfort ourselves with the knowledge that another London consultant placed our Dublin colleagues in a similar predicament by pronouncing tuberculosis non-contagious. As far as one can judge from the opening days, the exhibition promises to be a great success, and the programme of lectures by medical men is an excellent one. The Corporation proposed a little time ago to open a dispensary for the out-patient treatment of tuberculosis, but the Local Government Board have refused to sanction the scheme, saying that there is no power under any Act of Parliament for such a expenditure.

LETTERS TO THE EDITOR.

THE LATEST PHASE OF THE TRYPSIN TREATMENT OF CANCER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been drawn to a book published by Dr. C. W. Saleeby entitled "The Conquest of Cancer."

I feel bound to take some notice of this publication by reason of the fact that certain misrepresentations distributed throughout the book have been made in regard to my introduction of the method of treatment of inoperable cancer by trypsin, and the considerations which led me to it.

This is a book which purports to inform the public respecting the views now held by the scientific workers of the profession as to the present position of the cancer question, and the method adopted by the author of carrying out this design is that of abusing everyone who does not happen to agree with himself or Dr. Beard.

I do not deem it necessary to re-discuss the question of priority so far as the introduction of the trypsin treatment of cancer is concerned, inasmuch as my claims have been recognised by independent observers in the scientific Press of this country (vide *Nature*, January 10th, 1907).

But Dr. Saleeby would have his readers believe that Dr. Beard first suggested the treatment, and that I only employed or advocated it. After referring to a paper read by the latter in Edinburgh on December 13th, 1904, an abstract of which was printed in the *Lancet* of February 4th, 1905, he goes on to say:—"Only a few weeks after Dr. Beard's lecture, Dr. Shaw-Mackenzie began the hypodermic use of trypsin in cancer, and to him undoubtedly must be awarded the credit of being the first physician to employ the new treatment. . . . My purpose is to illustrate the conditions under which discoveries are made, and I will here quote from a private letter of Dr. Beard to myself:—'At once, December 8th, 1904, I got all my critical period preparations . . . and saw at once that I had neglected to lay stress as a character of the critical period on the commencing functional activities of the pancreas gland. So the problem was solved so far. The other thing is a later story. At once I saw there must be an antithesis of ferments, but was not aware whether any ferment had been described in the cancers. . . . January 18th, 1905. . . . Then it was you might have heard my heart thump. All was exactly as I had foreseen. . . .' This letter was not sent for publication, but I have taken the liberty of putting it on record for its personal and general interest."

It was on December 8th, 1904, as published by me in the *Lancet*, February 11th, 1905, I commenced investigations into the action of pancreatic and other ferments on glycogen. The considerations which led me to this were known to many, and published in a pamphlet of mine in October, 1904, in the *British Medical Journal*, January 7th, 1905, and the *Lancet*, January 14th, 1905; but I will here take the liberty of quoting from a letter of Dr. Beard to myself dated December 7th, 1905:—"When you get this letter on December 8th, it is a year exactly since you and I independently arrived at the trypsin idea. . . ."

The strenuousness of the efforts displayed by Dr. Saleeby in the lay Press, no less than in his book on behalf of the claim of another, must clearly demonstrate to any impartial person the weakness of his cause. If anything more was required it is the attempt to submit my work to destructive criticism. It is repeatedly reiterated that trypsin has no action on glycogen. "There is no ferment," he says, "which affects both proteids and carbohydrates, such as glycogen." This is simply begging the question. Observers of old regarded glycogen as starch in proteid combination, and the purest glycogen obtainable still contains nitrogen. Moreover, the action of the proteolytic ferment rather than the amylolytic was and is supported by the fact recently and independently testified to that glycogen exists in the living tissues as proteid-glycogen. Dr. Saleeby mentions Dr. Odier's work. He does not mention that in growths treated with a mixture of pancreas, liver and muscle extracts, coincident with atrophy of cells, histological examination has shown them to be deprived of glycogen. Drs. Saleeby and Beard attribute any action on glycogen to the leucocytes, forgetful that the digestive properties of these are attributed to a proteolytic ferment apparently identical with trypsin. This additional aid of the leucocytes and increase has long been recognised, and found expression in hypodermic injections of chian turpentine introduced by Col. T. Ligertwood, C.B., M.D., and myself three years ago. Most suggestive of the action on glycogen at the present time is that the pancreas produces an "activator substance for a glycolitic enzyme contained in other tissues." Whatever the explanation, it is obvious the glycogenic nutrition of cancer may be interfered with, whatever the precise nature of the cell proliferation, be it epithelial or "trophoblastic."

Again, while my theory of cancer by analogy with diabetes is noted, no mention is made of the clinical fact of alternation of diabetes and cancer in different members of the same family, which directly led me to the inference that if, as is well known in certain cases, diabetes is a pancreatic disease with defective ferment action, so also might carcinoma be. He notes my suggestion of premature ageing of the pancreas, only to reject it, and to advance on his own account a shortage of trypsin from "whatever cause." In this respect readers of my work will know that, in referring to the age incidence of cancer, I suggested also congenital imperfections, and in referring to cases of spontaneous cure I suggested the removal of inhibitory—*e.g.*, mental, nervous, trophic or chemical causes temporarily interfering with either the general or local supply of the proteolytic ferments.

I pass on to chapters on the preparations of the ferments and the details of treatment. Is there anything here which is not known or indicated in my book? Injections of trypsin were first prepared by Mr. F. W. Gamble, for me. Of early cases treated, two at the present time are apparently in good general health, 2½ and 2 years, whether it is due to treatment or not. The injections were sent to Dr. Beard, at my request, by Messrs. Allen and Hanburys for the purposes of Dr. Beard's experiments on mice, and full information and composition were given by me. As for technique and details of treatment—"hypodermal, oral, and local"—these were fully published by me (*a*), and Dr. Saleeby's recommendations are, so far as I can see, for the most part adopted from my work without acknowledgment. He differs essentially in the importance he attaches to amylopsin and in the additional recommendation of amylopsin injections.

I imagine that most persons will find the most effective commentary upon this and upon questions of the strength of trypsin solutions discussed by Dr. Saleeby, in a paper by Dr. Hald, of Copenhagen, published in the *Lancet*, November 16th, 1907, (*b*) in which the author shows that the so-called solutions of amylopsin actually contain an abundance of proteolytic ferment, and in which paper also the author independently establishes the potency of British tryptic preparations.

Yours faithfully,
J. A. Shaw-Mackenzie, M.D.Lond.

[We have already accepted the evidence in favour of Dr. Shaw-Mackenzie's priority of claim to the trypsin treatment of cancer as established. Dr. Saleeby has not favoured us with a copy of his book for review.—Ed. M. P. and C.]

DISEASES OF TWINS.

To the Editor of The Medical Press and Circular.

Sir,—As father of twin boys I am able to add a small contribution to the inquiry which Mr. J. Lionel Tayler makes in your columns. My boys have just entered upon their nineteenth year. For the first twelve years of their lives their physical characteristics as to height, weight, and measurements remained closely alike; but they were always markedly different in feature and in mental characteristics. They have since varied in physical development, and have shown more marked mental and intellectual differences. They are well formed, uncommonly good-looking boys, but not very powerful. Their permanent teeth are without blemish. Their temporary sets were of very good quality. The firstborn seems to have stopped growing at 5ft. 6in., and has the mental qualities of a superior man of business; the second born, still apparently growing at about the same stature as his brother, is mentally up to the level of an average "scholarship" boy at a public school, and is thinking (somewhat to my discomfort), in the present deplorable position of the profession, of being a doctor. At four years of age they had influenza together, and with the rest of the household. At fifteen, at a public school, they both became affected with the mild variety of purulent ophthalmia, which sometimes becomes epidemic in schools. At sixteen, at a public school, they had measles, one a fortnight after the other, and, later, German measles. Later again they had whooping cough at the same interval. This is their complete record of disease.

Yours, etc.,
Paterfamilias Medicus.

November 23rd, 1907.

A ROYAL COMMISSION ON QUACKERY.

To the Editor of The Medical Press and Circular.

Sir,—You ask for outspoken views on this most important and practical of professional topics. Here are mine. I fully believe in the practicability and hopefulness of a Royal Commission as explained during late years in your correspondence and editorial columns, and I agree as to the flimsiness of the objections to it, provided always that the profession will

(*a*) "The Nature and Treatment of Cancer" (Fourth Edition). By J. A Shaw-Mackenzie, M.D.Lond. London: Baillière, Tindall & Cox.

(*b*) Comparative Researches on the Tryptic Strength of Different Trypsin Preparations, and on Their Action on the Human Body." By P. Tetens Hald, M.D.

unite to carry the thing through. I view as either hypocrisy or twaddle the suggestion that the profession ought not to defend the simple public, and at the same time themselves, against the injuries of quackery, because the sole part of the profession is to succour the suffering and to work at science. This view has been put forth by members of the British Medical Association. The profession is the most altruistic existing, and its unselfishness would not be lessened if it boasted of as much consideration from the State as is accorded to veterinary surgeons and solicitors. The profession has always included in its ranks great numbers of men devoted to science; and through their discoveries and the work of medical men in promoting national sanitation, a great part of their sources of income has been done away with. This renders the obligation of the State to them all the greater. General practitioners, the bulk of the profession, are largely prevented from joining in scientific work under present conditions. Many of them are too badly off and dispirited, whilst those practising among the poorer classes are perforce dragged down to the intellectual level of their customers. The average general practitioner rarely has a chance of making a diagnosis in a case worth observation. The patient, fortified by a study of quack literature, makes his own diagnosis. He has headache, rheumatism, or "liver," as the case may be, and comes to the practitioner for "something to do him good"—something better than the quack nostrums with which he has been dosing himself. The practitioner knows that if he attempts to make a scientific diagnosis when this is necessary, he will not, in the majority of instances, be able to get any adequate payment for his trouble, even in the rare cases in which the patient will submit. So cases of incipient malignant disease and of all sorts of organic pathological activity go on from bad to worse, with no other treatment than useless or harmful drugging. My final view (for the present) is that if the coarser kinds of fraudulent quackery which appeal to the poor and ignorant were put an end to, not only would the mass of preventable human misery be at once largely diminished, but the general practitioner would be placed in a position in which he could act truly as a professional man, instead of as a tradesman, and his earnings would be increased to a degree raising him at least to a bit above the often degrading condition of hopeless shabby gentility in which he is at present forced frequently to remain.

I am, etc.,
An Obscure Practitioner.
November 21st, 1907.

WHY LET SCARLET FEVER SPREAD?

To the Editor of The Medical Press and Circular.

Sir,—I am not surprised to see it stated in the Press that London suffers from an epidemic of scarlet fever. It does not take the right way to prevent it—viz., to bring the earliest cases under medical inspection and care. This can be done by means of the Guardians of the Poor freely offering "medical relief" to all sick children whose parents are unable to pay for a doctor. Parents cannot tell whether a child's symptoms are those of scarlet fever or not, and they will not, under present circumstances, call in the Poor-law doctor if they can possibly help it, even though they cannot pay for one themselves. If they do apply to the Guardians, too often they are worried to repay the cost of medical relief, or made to come, like suppliants, before the board or the committee. They are treated like "paupers." A Medical Officer of Health once told me that "the poor did not mind having scarlet fever in their homes, but they did mind having the Poor-law doctor." This was not dislike of the Poor-law doctor, who was a kind and popular man, but they objected to the degradation and disagreeables connected with the Poor-law as it is administered by the Guardians and relieving officers. Now the receipt of medical relief does not disenfranchise, and the sooner the Guardians make it understood that those unable to pay for a doctor can have this help without difficulty or degradation, the better for the public health.

Of course the children have a legal right to medical relief, but Guardians can, and I fear often do, practically deprive them of it by discouraging applications in various ways. This, again, is partly due to the old-fashioned political economy, and to the Local Government Board inspectors, who think more about the diminution of "pauperism" than of the diminution of disease and death-rate. If the Local Government Board would issue a circular as to medical relief on the same excellent lines as the recent one as to midwives, much good would be done. Many of the poor, and many also of the Guardians, do not understand there is a legal right, and many of the poor do not know how practically to obtain it. The circular would be useful to all parties.

Yours, etc.,
J. Theodore Dodd, M.A.
Oxford, November 18th, 1907.

OBITUARY.

ROBERT J. PATON, M.D., C.M.Edin.

We regret to record the death of Dr. Robert John Paton, who died on November 16th from blood-poisoning, resulting on a slight scratch caused whilst conducting an operation. Dr. Paton, who was 45 years of age, and honorary surgeon to the Newport and County Hospital, five weeks ago, whilst performing an operation for appendicitis on a patient at the hospital, pricked his hand. Inoclation was succeeded by blood-poisoning. Dr. Paton was born in India, his father being Military Chaplain to the 72nd Highlanders. He received his early education at Dumfries, and subsequently at the Edinburgh University. For some time he was medical officer at the Crighton Lunatic Asylum, Dumfries, but about 16 years ago he went into practice at Newport. He obtained his M.B. at Edinburgh in 1886, and M.D. Edinburgh in 1899. Shortly after coming to Newport he joined the 2nd V.B. South Wales Borderers, and at the time of his death was surgeon-major of the battalion. He also took an active part in ambulance work, and was once tutor of the local railwaymen, and some of the Volunteer Ambulance Corps he trained saw active service in the South African war. His principal work at Newport, however, was as hon. surgeon to the Newport Hospital. He was also medical officer for the St. Woollos district of the Newport Union. He leaves a widow and one daughter.

SPECIAL ARTICLES.

ROYAL COLLEGE OF SURGEONS OF ENGLAND—ANNUAL MEETING OF FELLOWS AND MEMBERS.

The twenty-third annual meeting of fellows and members which took place at the Royal College of Surgeons on Thursday last was the best attended meeting for many years, nineteen fellows and 69 members being present. This was doubtless due to the fact that since the last annual meeting both the Society of Members and the Council of the College had been received at the Privy Council by the Lord President on the question of direct representation of members on the college council, the society having previously presented a memorial on the subject to the Prime Minister. The President of the College, Mr. Henry Morris, presided at the meeting, and opened the proceedings with a statement regarding the principal items included in the report of the council, which was laid before the meeting.

The President said that, with regard to the admission of women to the college diplomas, the council had passed a resolution in favour of such admission, and that if the Royal College of Physicians were favourable to the scheme a vote would then be taken of the fellows and members of the college. The council had decided that it was not desirable for the college to grant a Diploma in Tropical Medicine, but in order to give a *cachet* to successful students, they had decided to appoint assessors to be empowered to endorse the certificates in tropical medicine gained by the holders of the college's diplomas. With regard to the munificent gift of Mr. and Mrs. Bischoffsheim of £40,000 to the Imperial Cancer Research Fund, to celebrate the event of their golden wedding, the President made the interesting statement that, if happily the cancer research came to a successful termination, the interest on this sum would still be available for research into other diseases. As regards the council declining to take any action in the question of the representation of members on the college council, the President assured the meeting that the council was not actuated by any hostility or opposition to the members, but by the feeling that the suggested innovation was not in the nature of a desirable reform.

The resolutions, which were included in the last issue of the Medical Press and Circular, were all carried unanimously. Mr. F. W. Collingwood's resolution regarding the recognition of members of the college for becoming candidates for hospital appointments was seconded by Mr. H. Elliot-Blake; Mr. Joseph Smith's resolution re-affirming the desirability of admitting members to direct representation on the council was seconded by Mr. Brindley James, and a long debate followed on the question. Dr. W. G. Dickinson's resolution, in which he expressed regret that the report did not contain the reply of the Lord President of the Privy Council to the deputation of members of the college council, was seconded by Mr. S. C. Lawrence. Dr. Dickinson suggested that the advice given on behalf of the Government was that the council should obtain a new Charter, and that the action with reference to the admission of women to the examinations of the college was with the object of evading the necessity of getting a new Charter, because if a new Charter were granted for the admission of women to the examinations, it would have to include the admission of members to the council. The two resolutions standing in Mr. H. Elliot-Blake's name suggesting that the college and its work should join with the University of London so as to form an Imperial University of London, and that a hood should be added to the gowns worn by fellows and members, were seconded by Mr. Brindley James.

A vote of thanks to the President for presiding at the meeting concluded the proceedings.

MEDICAL NEWS IN BRIEF

Royal Army Medical Corps.

Captain H. R. Bateman has been appointed for special duty at the Royal Army Medical College.—Major S. F. St. D. Green has been appointed to the medical charge of the Louise Margaret Hospital for Women and Children, Aldershot.—Lieut. H. E. Gotelee, who has been doing duty at the Cambridge Hospital, has left Aldershot for Ceylon.—Capt. S. G. Butler, surgeon-in-charge of the Cambridge Hospital, Aldershot, has been ordered to embark for India. The November issue of the *Journal of the Royal Army Medical Corps* contains an important article by Surgeon-Lieut. E. L. Moss, who states that the rough flannel shirt issued to soldiers is responsible for some affections of the skin. He says: "As medical officer to the 2nd Battalion Royal Welsh Fusiliers, I have been greatly impressed by the number of men temporarily inefficient and requiring admission to hospital on account of boils and pustular skin infections, the result of scratching or chafing prickly heat. I have strong reasons for believing that the regulation flannel shirt is largely responsible for the condition."

Battersea "Brown Dog" Memorial

Ten students from Middlesex and University College Hospitals were charged on November 21st at the South-Western Police Court with causing wilful damage to the "Brown Dog" memorial at Latchmere Recreation Ground, Battersea, and after being sharply reprimanded and warned by Mr. Paul Taylor, they were fined £5 each. The "Brown Dog" statue was presented to Battersea by the International Anti-Vivisection Council, and was unveiled by the Mayor of Battersea in 1906. The inscription on it is in these terms:—"In memory of the brown terrier dog done to death in the laboratories of University College in February, after having endured vivisection extending over more than two months, and having been handed over from one vivisector to another till death came to his release. Also in memory of the 232 dogs vivisected in the same place during the year 1902." The dog is seated above a drinking fountain, at the base of which are the words: "Men and Women of England! How long shall these things be?" Mr. Paul Taylor said the erection of the momerial was perfectly legitimate, and the defendants should remember that there was another side to the question which they regarded as personal to themselves. He could not regard anything as more serious than the assembling of 500 students, for such conduct was calculated to lead to a public riot. He warned defendants if such conduct was repeated the offending persons would go to prison for two months without the option of a fine.

Assault on a Medical Man.

Mr. E. C. Hughes, of Guy's Hospital, was the subject of a serious assault in Soho on November 22nd. His assailant was a smartly dressed young woman, who went up to him as he left a hospital in Dean Street. She was carrying an innocent-looking brown paper parcel. There was an altercation between the two, which was cut short by Mr. Hughes saying, "If you follow, I shall give you in charge." Thereupon the woman struck him a blow on the side of the head with the parcel, which contained a heavy iron hammer. Mr. Hughes reeled and blood flowed from his head; he was only saved from falling by an onlooker. The woman was arrested and taken to Marlborough Street Police Station. Mr. Hughes went in a cab to Guy's Hospital, where it was stated last night he was suffering from a severe scalp wound.

Poor Law Medical Officers and the Supply of Expensive Medicines.

Recently, in approving the appointment of a District Medical Officer in the St. Germans Union, the Local Government Board informed the Guardians that they were of opinion that it was desirable that expensive medicines should be supplied to the sick poor at the cost of Boards of Guardians, and not at that of the Medical Officer, and requested the Guardians to take this opportunity of considering the matter with a view to the adoption of such an agreement. The Guardians decided to reply to the effect that it was not their custom to do as suggested. They had confidence in their medical officers to give the best medicines where needed, and that if the Local Government Board insisted on their suggestion being carried out in this case they would have to consider the position of the whole of the medical officers. So far no complaints had been received.

The Asylums Board and Bacteriology.

The Local Government Board having expressed their willingness to assent to a proposal to erect bacteriological and anti-toxin laboratories at Belmont, and the anti-toxin stables recently erected there being in working order, the Hospitals Committee of the Metropolitan Asylums Board have now decided to recommend the Board to appoint Dr. C. E. Cartwright Wood as bacteriologist at their establishment at a salary of £600 per annum, with an assistant at a salary of £300 per annum.

Trinity College, Dublin

The following candidates have passed the Final Medical Examination (Part II.), Michaelmas Term, 1907:—Surgery: George F. Graham (Passed on High Marks), Robert A. Askins, Wilfred J. Dunn, Julian B. Jones, Bethel A. H. Solomons, Thomas P. S. Eves, Henry D. Woodroffe, Francis O'B. Kennedy, James D. K. Roche, Wilfred L. Hogan, Henry J. Keane, Archibald L. Robinson, James R. Yourell, Joseph H. Elliott, James G. M. Moloney.

Society of Apothecaries of London.

The following candidates having passed the usual examinations, have received the L.S.A. Diploma of the Society entitling them to practise Medicine, Surgery and Midwifery:—M. F. Emrys-Jones B. S. Matthews, J. F. McQueen, G. H. Rodolph, and A. L. Walters.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

***Specially compiled for* The Medical Press and Circular.**

RECENT PATHOLOGICAL LITERATURE.

Toxicity of Therapeutic Sera.—Besredka points out that most therapeutic anti-sera possess (*Annales de L'Instit. Pasteur.*, No. 10, 1907), in addition to their anti-toxic properties, a certain amount of toxicity, which may show itself by the occasional manifestation of unpleasant symptoms following the therapeutic application of these sera. He has been able to estimate the degree of this toxicity by subdural injections of the sera into healthy guinea-pigs, and has been able to demonstrate certain facts thereby. The more important are as follows:—(1) The sera of horses living under similar conditions are of the same degree of toxicity; individual differences are rare and of little importance; (2) the variable toxicity of sera appears to depend partly on their age and partly on their origin; (3) all sera are very toxic on the day of the bleeding, but they lose their toxicity gradually in keeping. No therapeutic serum, however, should be used within two months of the date of bleeding. (4) Any serum which produces toxic symptoms in guinea-pigs in doses of 1-16 to 1-20 c.c. should be regarded as too toxic for use. M.

Immunisation Against Inoculated Cancer.—Bridré (*Annal. de L'Instit. Pasteur.*, No. 10, Oct. 25th, 1907) has carried out experiments with the object of establishing, if possible, a condition of immunity or increased resistance in mice to inoculable tumours. As a subject for experiment he chose a tumour of an adeno-carcinomatous type, which gave from 30 to 40 per cent. of successful results when injected subcutaneously He found, in the first place, that mice which failed to develop the tumour on a first inoculation very often developed it on a second occasion, and did not appear to have acquired any degree of immunity from the first injection. Those, however, who received two inoculations without developing a tumour remained immune as a rule when subsequent injections were given. Injections of fresh cancerous tissue were found in all cases to be more valuable than similar injections of desiccated cancerous material. It was found, however, that injection of normal tissues of a mouse also conferred a heightened resistance, and from this he concluded that the immunity could not be specific. The increase in resistance in all cases was proportional to the amount of tissue injected. M.

Surra in Indo-China.—Schein has studied exhaustively the diseases caused by trypanosomes in cattle in Indo-China, and to which the general term of surra is applied (*Annales de L'Institut. Pasteur*, September, 1907). He has come to the conclusion that although marked variations are noted in the course of various epidemics, still all the epidemics are due to the same trypanosome. The variations he attributes to what he terms the genealogy of the particular parasite in any case. He finds also that the buffalo is not protected after a single attack of surra, and that it can in many cases be the carrier of virulent parasites without itself showing any symptoms. Infected cattle, moreover, may be found outside the area of the epidemic regions. As aids to the extermination of the disease he recommends drainage and clearing of the country, filling up of stagnant pools, careful choice of pasture lands, careful segregation of diseased animals, and occasional systematic examination of healthy animals. M.

Staphylococcal Vaccines in the Treatment of Furunculosis.—Hartwell and Lee (*Boston Med and Surg. Journal*, October 17th, 1907) report the result of their observations on 100 cases of staphylococcal infections treated by Wright's methods. They have found that it is unnecessary in such cases to make use of a vaccine prepared from the actual organism that is causing the individual lesion, but that a stock vaccine of any staphylococcus aureus will do. In their earlier work the opsonic index was taken regularly, but later they found that equally good results could be obtained without the index by giving routine doses every four days of from 300,000,000 to 600,000,000 micro-organisms. The inoculations are made subcutaneously and at a fresh site on each occasion. They summarise their conclusions as follows:—(1) The vaccine treatment is the most effectual of all treatments for boils and carbuncles; (2) although this treatment does not prevent recurrence, cases of chronic furunculosis can be absolutely controlled by occasional inoculations; (3) the determination of the opsonic index is quite unnecessary, and the treatment can be carried out without special technical training. M.

Pain and Blood-Pressure.—Auschmann has carried out a series of experiments with the object of determining the influence of pain upon blood-pressure (*Münch. Med. Woch.*, October, 1907), and records his results. His method consisted of applying painful electrical stimuli to various groups of individuals, and recording the blood-pressure before and after the application. Twenty individuals with normal sensibility were so tested, and in 18 there was a rise of from 8-10 m.m. of mercury. In persons with a neurotic temperament and a high preliminary blood-pressure the elevation produced was still greater. If the sensibility is disturbed in any way, either as the result of functional or organic disease, the rise in pressure does not take place. M.

Epidemic Pneumonia.—Fabyan writes on the above subject, and points out that while many writers have called attention to cases of pneumonia occurring in groups, the actual occurrence of such cases is comparatively rare. He himself has lately observed such a group, which he now reports (*Johns Hopkins Hosp. Bulletin*, Nov., 1907). The epidemic occurred in a family of ten members, nine of whom were living in the same house. Out of these nine, six members developed acute pneumonia within a period of ten days. Two other members developed an illness characterised by headache and fever, and abdominal pain, within the same period, but no physical signs were found in the lungs. One case proved fatal, and the necropsy showed a typical croupous pneumonia, of a pseudo-lobar type, while from the same individual during life pneumococci were obtained on culture from the circulating blood. It was noted that where two of the patients slept together, the second infection followed the first in each instance in from six to nine days. M.

The Metabolism in Leukæmia Treated by X-Rays.—Finne reports the results of his investigations in four cases of myelogenous leukæmia treated by daily exposure of the splenic region to the X-ray emanations for a period of about 20 minutes (*Russische. Med. Rundschau.*, Heft. 8, 1907). During the treatment frequent blood examinations were made, including counts of the red and white cells, hæmoglobin estimation, and a differential white cell count. At the same time the nitrogenous urinary output was determined, and a quantitative estimation made of the purin substances and uric acid excreted. The writer concludes that the X-rays give much better results than can be obtained by any other treatment, and that in most cases all leukæmic symptoms disappear, so that a complete cure results, at any rate for the time being. The best results are obtained in the myelogenous form of the disease, and they do not appear suddenly, but gradually develop. Apparently the rays influence the disease process itself, but since the etiology is unknown, nothing definite can be stated on this point. The diminution in number of the leucocytes seems to be due to the fact that they are produced in smaller numbers, inasmuch as their diminution goes hand-in-hand with a lessening of the output of purin bodies and uric acid. At the commencement of treatment a decrease in the output of these substances took place, and continued till the leucocytes had fallen to about the normal number. If the exposures were continued after that time, the excretion of purin bodies again increased, apparently due to the destructive effect of the rays on tissue cells of the body. M.

Amaurotic Family Idiocy.—Cohen and Dixon report a case of this disease in which the eyes were enucleated for examination within three hours after death (*Jour. Amer. Med. Assoc.*, May, 1907). The histological changes detected were, swelling of the multipolar ganglion cells, displacement of their nuclei, retraction of cell reticulum, diminution in number of ganglion cells, and disappearance of Nissl's granules. By Weigert's stain, dark granules were found in all the ganglion cells, and it was found that at the macula lutea there were several layers of multipolar cells, while beginning simple atrophy of the optic nerve was also noted. They think it likely that the primary change in the disease is an arrested development, followed by degeneration caused by toxins, the result of defective metabolism. M.

Blood Pressure in Tuberculosis.—Stanton has made a study of the blood pressure in over 200 cases of tuberculosis by means of a modified Riva-Rocci instrument (*Internat. Clinics*, Vol. III., 1907), and has come to the following conclusions:—(1) The blood pressure, both systolic and diastolic, is generally low in tuberculosis, and, as in normal cases, is lower in women than in men; (2) the pressure is higher in improving cases and lower in progressing and unfavourable cases; (3) hæmoptysis is not accompanied by any change in the pressure; (4) the nephritis of tuberculosis apparently does not increase the blood pressure; (5) time of day, presence of fever, degree of involvement, have no influence on the blood pressure of tuberculosis. M.

Diagnosis of Typhoid Fever by the Conjunctival Reaction.—Chantemesse has been experimenting with typhoid fever patients in the hope of discovering an ophthalmic reaction in them similar to what Calmette has described in tuberculous patients when tuberculin is dropped on to the surface of the conjunctiva. He has carried out his observations (*Deutsch. Med. Woch.*, 1907, No. 39) on 120 patients altogether, out of whom 50 were healthy, and 70 were ill with enteric fever. The healthy individuals in all cases failed to react, while a reaction was obtained in all the others, and this reaction was often obtained earlier than the Widal reaction, and was often less equivocal. The writer believes that the reaction gives a new aid to diagnosis, which may be employed and relied on almost as soon as the earliest clinical symptoms are developed. M.

Vaccine Treatment and Diagnosis.—Wright and his colleagues in the Laboratory of St. Mary's Hospital publish (*Lancet*, November 2nd, 1907) "a collection of some of the more interesting" of their records in regard to therapeutic immunisation. The points touched on are very numerous, and we regret that we cannot give a detailed analysis of the paper, which, however, should be read in full. The authors show that auto-inoculation is not infrequent in the beginning of tuberculous infection, and that it is a regular accompaniment of the hectic fever of advanced phthisis. In reference to a case of gonococcal arthritis they show that there is an intimate relation between auto-inoculation and auto-immunisation on the one hand, and the clinical symptoms of the patient on the other. With regard to generalised bacterial infections, they show that spontaneous auto-inoculations and immunising responses are a characteristic feature in anthrax septicæmia as seen in rabbits. The history of their vaccine work in regard to streptococcal and staphylococcal septicæmias is set out in some detail. The authors conclude the first part of their paper by considering the effect of massage and of active muscular movements, the effect of operative interference with the foci of disease, and the effect of active and passive hyperæmia, in producing auto-inoculation and auto-immunisation. In the second part of their paper the authors bring forward evidence to show that in the induction of an auto-inoculation, when this is preceded and followed up by a series of measurements of the opsonic index, there is at hand a method which will aid in some of the diagnostic and therapeutic problems which present themselves for solution in connection with localised infections which are not accessible to direct bacteriological examination. The records and chart contained in the paper are certainly interesting, some of them dramatically so. Particularly are to be noticed certain charts showing a very remarkable parallelism between the opsonic power and the temperature, and between the opsonic power and the symptoms, in various cases. The table of thirty cases where some important question of diagnosis or treatment was answered by the results of auto-inoculation, gives examples of a great variety of cases, and of the dogmatic answers which the authors think were justified. The paper, as a whole, is of great interest, but we are among those who think that selected cases, no matter how striking, do not give a just view of the results of a method of treatment or diagnosis. Vaccine treatment has justified itself, not only in the hands of Wright, but of his disciples all over the world. The necessity for opsonic control is, however, not yet established, and it cannot be so long as Wright publishes only selected cases. Until a full account of the work at St. Mary's is published, including not only ten "more interesting," but all the cases, favourable and unfavourable, if there be any such, no decided opinion can be come to as to the necessity for opsonic control of vaccine treatment. R.

Typhoid Agglutinins in a Non-Typhoid Case.—Symmers and Wilson (*British Medical Journal*, September 21st, 1907) report a case of cerebro spinal fever, in which the blood gave a positive Widal reaction to the typhoid bacillus. The patient was a woman of 27 years of age, who had had no previous illness of any sort for nineteen years, since as a child she had suffered from scarlet fever. It was, therefore, unlikely that she had ever had typhoid fever. Her clinical symptoms were those of cerebro-spinal meningitis, which was epidemic in Belfast at the time of her illness there. Her blood was twice tested as to its agglutinative powers on the *Bacillus typhosus*, and on both occasions the serum in dilutions of 1 in 200 gave marked clumping within fifteen minutes. The illness having ended fatally, an autopsy was performed, and the clinical diagnosis confirmed. There was suppurative meningitis of the brain and cord, and from the pus was recovered in pure culture and in great abundance the *diplococcus intracellularis meningitides* of Wiedaselbaum. An exhaustive bacterioscopic examination of the spleen, mesenteric glands, and urine, was made for the typhoid bacillus, with negative results. There were no lesions of the intestine to suggest typhoid fever; the Peyer's patches being normal. The strain of typhoid bacillus used in Widal's test was that customarily employed in Symmers' laboratory; during the past year it gave in 112 examinations results which, clinically controlled, were considered correct in 97.3 per cent. of the cases. The case recorded is of interest from two points of view—(1) The presence of a typhoid agglutinins in the blood of a case which was not typhoid fever. (2) A possible peculiar property of the serum in cerebro-spinal meningitis on other bacteria than the specific coccus.

The presence of typhoid agglutinins in other conditions than typhoid fever has often been recorded. The present abstractor frequently examined the blood of one of his colleagues who had never had typhoid fever, and who was in robust health; his blood invariably gave positive results to Widal's test, even in high dilutions. R.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

S. R. P. (Croydon).—The method of injecting air subcutaneously for the relief of certain painful manifestations, such as sciatica, was introduced by Dr. Cordier, of Lyons, and the results in the hands of other practitioners has been, on the whole, good—sometimes, indeed, brilliant.

UBIQUE.—Peroxide of hydrogen, in ten-volume strength, has been found very efficacious in cases of epistaxis. A pledget of wool soaked in the fluid is pressed by the finger against the bleeding spot, and after some moments the hæmorrhage generally ceases.

M. D., L. S. A. (Leeds).—Strophanthus acts more quickly upon the heart than digitalis, owing to its being more readily absorbed. Moreover, its action is less irritant.

A COMMON OCCURRENCE.

When a patient calls to see you,
  Very anxious to be cured,
And he quite forgets to fee you—
  Say; now can this be endured?
Take a lesson from the Lawyer;
  He's not one to trust to fate.
No advice, or pen to paper,
  Till he's *sure* of six and eight.
Doctors still are far too willing;
  Free advice should be abhorred.
Public fight about a shilling;
  Go their way: nor thank the Lord!

A. D.

UGANDA.—It cannot be too clearly stated that Dr. Koch no more discovered atoxyl and its value in sleeping sickness than that he discovered the moon. The credit, such as it is, is due to Drs. Thomas and Breinl, of the Liverpool School of Tropical Medicine. According to the newspapers, Dr. Koch discovers everything.

F.R.C.S.Edin.—It is not usual in England to omit "Edin." after F.R.C.S. in cases where the diploma has been obtained in Scotland.

SATURN.—Our correspondent had best arrange a consultation with a specialist in children's diseases.

DR. SYDNEY, W. S.—We shall be pleased to receive the notes, and, as far as our engagements permit, will give them early publication.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 27TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. P. Paton: Clinique (Surgical.) 5.15 p.m.: Lecture:—Dr. W. Milligan (Manchester): Some Practical Points in the Treatment of Suppurative Disease of the Nasal Accessory Sinuses.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

THURSDAY, NOVEMBER 28TH.

CHILD STUDY SOCIETY (Parkes Museum, Margaret Street, W.).—8 p.m.: Lecture:—Dr. A. H. Hogarth: The School Clinic.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. P. Horrocks: Profuse Menstruation (with illustrative cases).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture:—Dr. A. E. Giles: Ultimate Results of Inoperable Gynæcological Cases.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Coccus Diseases: I., Impetigo Contagiosa; II., Furuncle; III., Carbuncle; IV., Coccogenic Sycosis.

HOSPITAL FOR SICK CHILDREN (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Thompson: Jaundice in Children.

FRIDAY, NOVEMBER 29TH.

SOCIETY OF ARTS (John Street, Adelphi).—8 p.m.: Shaw Lecture:—Dr. J. S. Haldane: The Hygiene of Work in Compressed Air (Diving, Caisson Work, etc.).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. E. Clarke: Clinique. (Eye.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Appointments.

FALCONER, A. D., M.D.Aberd., M.R.C.P.Lond., House Physician at the Bristol Royal Infirmary.

HIBBERT, C., M.B., Ch.B.Vict., House Surgeon at St. Mary's Hospital, Manchester.

JOSCELYNE, ARTHUR EDWIN, L.R.C.P.Lond., M.R.C.S., L.S.A., Public Vaccinator for Taunton

LACEY, FRANK HAMILTON, M.B., Ch.B.Vict., House Surgeon at St. Mary's Hospital, Manchester.

MEADOWS, GEORGE STEPHEN, M.B., C.M.Edin., Medical Officer for Health of Saltash (Cornwall).

SHEPPARD, ARTHUR LEWIN, M.B., B.S.Durh., Senior Resident Medical Officer at the Bristol Royal Infirmary.

Vacancies.

Castlebar District Lunatic Asylum.—Assistant Medical Officer. Salary £100 per annum, together with annual allowance (including £50 in cash) valued at £100. Applications to Joseph F. Kelly. (See advt.)

Cavan Union.—Medical Officer. Salary £100 per annum. Applications to Joseph Gur, Esq. (See advt.)

Seamen's Hospital Society, Greenwich, S.E.—Medical Superintendent of the Dreadnought Hospital, Greenwich. Salary £200 per annum, with board in the Hospital. Applications to P. Michelli, Secretary.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon. Salary £20 for six months, washing allowance £2 10s., with board and residence in the Hospital. Applications to the Secretary. (See advt.)

London County Asylum, Long Grove, Epsom, Surrey.—Fifth Assistant Medical Officer. Salary £150 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 6, Waterloo Place, S.W.

West Riding Asylum, Wakefield.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, washing and attendance. Applications to the Medical Director at the Asylum.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C.—Bacteriologist. Salary £120 a year, with lunch in the Hospital. Applications to the Secretary.

Norwich City Asylum, Hellesdon-next-Norwich.—Assistant Medical Officer. Salary, £130 per annum, with rooms, board (no stimulants), laundry, and attendance. Applications to the Medical Superintendent.

Essex County Asylum, Brentwood.—Fourth Assistant Medical Officer. Salary, £150 per annum, with board, etc. Applications to the Medical Superintendent.

Births.

ALLWORTH.—On Nov. 23rd, at "Fairholme," West Hill, Sydenham, the wife of A. Leigh Allworth, M.R.C.S., L.R.C.P., L.D.S., of a son.

BARRY.—On Nov. 19th, at Ashfield Park House, Terenure, the wife of Dr. P. J. Barry of a son.

ELLIS.—On Nov. 19th, at 157, King Henry's Road, South Hampstead, London, the wife of Captain W. F. Ellis, R.A.M.C., of a son.

Marriages.

COLWELL—WOOD.—On Nov. 23rd, at Holy Trinity Church, Stroud Green, London, Hector A. Colwell, M.B., son of Mr. and Mrs. Alfred Colwell, of Ridge Road, Hornsey, to Clara Elizabeth, eldest daughter of Mr. and Mrs. J. Wilson Wood, of Ridge Road, Hornsey.

HAYES—ROYDS.—On Nov. 20th, at Bombay, India, Arthur Herbert Hayes, captain R.A.M.C., son of the Rev. A. H. Hayes, Rector of All Saints', King's Lynn, Norfolk, to Kathleen Mabel, eldest daughter of the late Ernest E. Molyneux Royds, of Rochdale, Lancashire.

Deaths.

HASARD.—On Nov. 20th, at Melbourne, Derbyshire, John Hasard, M.R.C.S., L.S.A., aged 63.

McEWEN.—On Nov. 21, at Pen Rallt, Abergele, Margaret Emma relict of William McEwen, M.D., late of 26, Nicholas Street, Chester.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, DEC. 4, 1907. No. 23

NOTES AND COMMENTS.

Academic and Scientific.

THE annual meeting of the Royal College of Surgeons of England found the Council in still the same spirit of obduracy with regard to the claims of members for representation on the governing body. It seems that the Council, after considerable search for an excuse for the attitude of "what is our own we'll hold," to which they have clung so tenaciously through good and evil report, have lighted on an admirable one, namely, that the "functions of the College are academic and scientific, and are exercised by the Council for the public welfare, and not as a trust received from the members." After this the members may take heart of grace, for if this is the best the Council can say for themselves they must be in a parlous state. It would be interesting to hear how the Council have sought to serve the public welfare, and how much they have sacrificed to that noble ideal. We search our memories in vain for any striking example. The claims of the Council that they are not exercising a trust received from the members is certainly in accordance with its deeds. It does not exercise the trust received from the members at the reconstitution in 1843; but there is no need to glory in the fact. The conception of the Council of the function of the College is weird in the extreme. It is "academic," but it does not teach, it is "scientific," but it does not pursue research. The bulk of its income is received from members' fees, and these it uses not as a trust for the members but for the public welfare. Does the Council really contend that members pay fees in order that the public may be protected from them (the members)? Was ever more disingenuous stuff put forward to bolster up a shaky case?

The "Brown Dog" Disturbances.

THE disturbances among medical students with regard to the "Brown Dog" incident and their treatment by Mr. Paul Taylor, are much to be regretted. If we were to say that they were only the natural outcome of provocation, the phrase would be widely quoted by those papers which delight to calumniate the profession, and we should be accused of "encouraging" the disturbances. We do not say so, but we repeat what we said last week, that the monument and the inscription remain a standing menace to the reputation for good conduct that London medical students have gained. The recent disturbances have allowed to overflow the pent-up hatred felt by certain classes towards medical science and medical men, a hatred which is fomented by certain journals for political ends, regardless of fact, truth, justice, or honour. It is instructive to note the unctuous snobbery of such journals. The medical student, whom they have their knife into, is assailed with abuse and sarcasm, while the young lord who gets drunk and smashes windows, or the budding politician who removes the hands from a public clock, is applauded as a venturesome and dashing fellow. Of the ragging medical student, however, we hear "Is this the sort of man who is to attend our wives and daughters?" or that he is brutalised by vivisection. The Battersea Borough Council, as a whole, would seem to adopt much the same attitude, for the Finance Committee of that body, in presenting its report last week, mentioned that they had gone out of their way to instruct the Town Clerk to convey to the police, and especially to the two officers who arrested the students, the Council's appreciation of their services.

The Better Way.

A CORRESPONDENT of the *Standard*, writing on the subject, expresses with admirable taste the feelings that medical men and physiologists feel with regard to the animals that are experimented on. In remarking on the inscription he says, "Can we be expected to regard this egregious inscription, perpetuated in stone, without some impatience?" and a little later proceeds, "Had the inscription run somewhat as below, it would have been more humane and nearer the truth :—

"In memory of the Brown Dog, who died as he lived, a true friend to man and to his kind. His life taught a lesson of fidelity and devotion to duty, and his death was a sacrifice for the welfare of others like him, and for man, whom he loved.

"People of England, remember this."

Thus speaks the true humanitarian, and the true lover of dogs. His mouth is not froward, and he does not seek to use the regrettable sacrifices that the conditions of life necessitate to impugn the good feeling of those who support experimentation any more than he would seek to impugn that of a general who ordered his army to advance when there was a certainty of loss. But among certain classes the spirit against medical men that has been bred by anti-vivisectionists and others of their kidney, is of a bitterness and malignancy which no one would believe who has not had experience of it.

"Almost Manslaughter."

AT an inquest held at Tottenham the other day, some unusually interesting facts came to light, and we recommend them to the notice of the Committee of the General Medical Council which is to inquire into quackery, and on which we have elsewhere congratulated the new direct representatives of the profession. The facts are that a fish salesman at Billingsgate was pricked in the thumb by the "thorn" of a skate, and suffered from an inflamed finger in consequence. Now it seems that one Gregory, who had been a fish salesman, found surgical practice more lucrative than his own business, in consequence of having acquired a reputation for dealing with poisoned hands with a certain salve and plaster. This salve is stated to have consisted of marsh-mallow leaves, elderberry leaves, and parsley-tops, while the plaster was one of resin and turpentine. To Gregory the wounded salesman resorted and was charged two guineas for the treatment. However, he died of septicæmia. The coroner said that Gregory's treatment was quackery, and it was either crass ignorance or arrogance which led him to take the case up. Indeed, it was "almost manslaughter." The jury censured Gregory, who is, of course, now free to earn many more guineas in the same way, just as he admits having already "cured" hundreds in the market. It would be difficult to find a case better illustrating the conditions of unqualified practice. These salesmen apparently could produce two guineas for Gregory's precious remedies, when a doctor might have got a shilling or half-a-crown, and a hospital nothing. Had the patient been under qualified care the finger would probably not have been allowed to transmit its fatal effects to the system.

A Nose —not Ducal.

An interesting comment on the state of the law with regard to medical practice was furnished by an action in the Westminster County Court last week, when the "Derma Featural Company" sued a Mr. Spencer for the balance of fifteen guineas, £7 of which had been paid, for "building up a new nose." The defendant pleaded infancy, but the plea was disallowed and an order made for the payment of five shillings a month. We do not pretend to know what range of treatment the "Derma Featural Company" undertake, but as one of the advantages of being on the *Medical Register* is that it confers the right to sue for fees for medical treatment, we cannot understand how this Company can successfully use the County Court for the recovery of fees for a surgical operation. It is to us inconceivable that a new nose can be "built up" by other than a cosmetic surgical process, and therefore the *locus standi* of the Company is not apparent. If registrars accept death certificates from unqualified persons, or give burial orders without certificates, and if "Derma Featural" companies can recover fees for surgical operations and medical treatment, the advantages of registration seem to be that a medical practitioner is subject to supervision without any corresponding benefit, whilst outsiders have the advantages without any restrictions.

LEADING ARTICLES.

A PORTENT FROM THE GENERAL MEDICAL COUNCIL.

"The mills of God grind slowly, but they grind exceedingly small," is a comfortable maxim to the philosopher, although it savours too much of procrastination to the man of action. The slow evolution of natural laws in social relations presents us with the series of adjustments and readjustments, sometimes quiet and gradual, sometimes violent and revolutionary, which, taken together, constitute history. As regards the particular subject of medicine, mediæval ignorance has given way to twentieth-century exactitude, and legitimate medical practice has emerged from the craft of the leech, the apothecary, and the barber to the dignity of the duly qualified modern medical practitioner. Side by side with this happy advance there has been no corresponding diminution in the evil work of the quack and the charlatan, whose methods are much the same, whether we read them in black-letter or in the columns of a London newspaper of to-day. The form is somewhat changed, but the substance is the same. The quack of Queen Elizabeth's time was able to deceive his customers with a far less expenditure of capital and brains than is needed by the proprietary medicine vendor of to-day. For many years the "Medical Press and Circular" has almost alone of the medical journals waged an unceasing war against quacks and quackery. In the interests of the public, no less than that of the medical profession, we have done what we conceived to be our duty in the matter, without fear and without favour. In this case it must be admitted that the mills of God have indeed ground exceeding slow, but we trust that within the next generation the curse of medical quackery will be crushed with remorseless grip betwixt the upper and the nether millstones. Of late the subject has been discussed more or less seriously by some of the medical societies and journals. For obvious reasons the lay newspapers, which draw vast revenues from the advertisements of quacks and quackery, will give no hand in the campaign. At length the General Medical Council have taken action in the important matter of unqualified practitioners. Not the old familiar Council, be it noted, as known to us for many years past, but that part of it which comprises the recently elected direct representatives, Dr. Langley Browne, Dr. MacManus, and Dr. Latimer. The original proposition, withdrawn later in favour of another, ran:—

> "That this Council, deeming it to be contrary to the public interest that any person other than duly qualified practitioners in medicine and surgery should practice medicine in Great Britain and Ireland, appoint a Committee to draft such amendments of the Medical Act as may be necessary to secure this prohibition, and to report to the Council at the session in May."

This proposal was met with a not unfamiliar jeremiad from the conservative members of the Council, who talked about the necessary education of the public, the improbability of obtaining legislation, and the vested interests that would be roused into opposition. Finally, however, the following resolution was unanimously adopted:—

> "That a Committee be appointed to report upon all the legal provisions existing in the Colonies and Dependencies of the Empire, and in foreign countries, for the prevention of medical practice by other than legally qualified persons, and to consider what steps should be taken to procure effective legislation for the same purpose in Great Britain and Ireland."

It is to be hoped that this event marks a new era in the history of the General Medical Council. Unless that body becomes inspired with some of the wider and more generous impulses of modern collectivism, it seems not improbable that it will drift into the position of a hopelessly effete administrative instrument. It is not a little significant that this most promising resolution has come from the representatives of the general practitioners. That fact, to our mind, strongly supports the contention that the constitution of the Council demands remodelling on the lines of a representative democratic as against its present individualistic basis. Meanwhile we congratulate the direct representatives on having at any rate fired the first official shot in the campaign. The names of the committee appointed to report are as follows:—Dr. MacManus, Dr. Latimer, Dr. Norman Walker, Dr. Kidd, Dr. Saundby, Sir John Moore, Mr. Henry Morris, and Dr. Langley Browne.

THE CLAIM TO PRIORITY IN TRYPSIN TREATMENT OF CANCER.

THE unwritten laws of the medical world, if at times of a somewhat misty nature, are on some points abundantly clear. One of the clearest of these directions is to avoid, above all things, the discussion of technical medical matters in lay newspapers. That rule has lately been thrown to the winds by certain members of the profession with an audacity and a persistence that is unparalleled in the annals of medical history. In some cases the offenders are engaged in actual practice; in others they may not see patients; but in either event we imagine that it is not altogether improbable that the attention of the General Medical Council will at no distant date be called to this undesirable conduct. On ethical grounds it is not easy to imagine why a man who has scientific facts to discuss prefers to submit them to the judgment of the public while they are still being investigated and criticised by medical men, whose opinion on such matters is alone of value. An instance of the kind may be found in a book recently published by Dr. C. W. Saleeby, an M.D. of the University of Edinburgh, who is generally understood not to be engaged in actual practice, In the book in question, to which our attention was drawn by a correspondent in our last issue, the author lays down the law upon cancer with an emphasis and a conviction that has no rival in the works of scientific surgical authorities. Moreover, he deals freely with the dangerous weapon of personal abuse, a fact that obviously does not strengthen his position. In his desire to attribute the credit of the introduction of trypsin to a non-medical investigator—Dr. Beard, of Edinburgh—he goes to extremes that are calculated to defeat his object. With regard to priority of claim to the trypsin treatment of malignant growths, we have, after careful consideration, ascribed the credit of originality to Dr. J. A. Shaw-Mackenzie. The evidence in favour of that view appears to us overwhelming, and so far as we can ascertain has not been seriously discussed either by Dr. Beard or by Dr. Saleeby. The plain fact of the matter appears to be that both Dr. Shaw-Mackenzie and Dr. Beard arrived at the theoretical value of this special line of treatment by independent routes, but Dr. Shaw-Mackenzie was the first actually to treat patients. It is surprising, therefore, that Dr. Saleeby should in his book attribute absolute priority to Dr. Beard. The allowances that have been made for Dr. Saleeby both by his professional brethren and by the General Medical Council have been great, but the latitude of privilege must necessarily reach a limit when he elects to discuss the action of particular individuals, and he will be at once challenged to make good his statements. In settling a point of priority of claim to a discovery, we must look to something more than the *ex parte* statements of a heated partisan. The clamour and violence of the market-place must give way to the calm and dispassionate investigations of the court of justice. So far the stage thunder seems to have come from Dr. Saleeby, and the argument, clear and supported by documentary evidence, from Dr. Shaw-Mackenzie. It is intolerable that any men claiming the ear of the public as Drs. Beard and Saleeby have done should refrain from substantiating the claim they make to priority, a claim which has already been strongly challenged. If they are to maintain their position as men of honour and responsibility they will either take steps to prove their assertions up to the hilt, or else will withdraw them for all time. The matter is capable of proof or disproof. There appears to be a growing conviction in the orthodox medical world that the trypsin treatment of malignant growths, although not in itself a final solution of the problem, has nevertheless advanced our general conceptions of the nature and treatment of cancer in a way that is not a little noteworthy. For even the faintest ray of light cast upon this mystery all who love humanity and all who are devoted to the pursuit of medicine will be profoundly grateful. In any case we think that the time has come when the claims of Dr. Shaw-Mackenzie in this matter should be authoritatively considered by the medical profession. Possibly the Cancer Research Fund would appoint a committee in conjunction with delegates from some of the leading professional bodies for the purpose of investigation and report.

CURRENT TOPICS.

Colonial Appointments.

THE Colonial medical service may in some instances be worth the attention of young medical men. It is now for the most part essential that the applicant should have gone through a special course of study in tropical medicine. Provided that a man be duly qualified and registered, and can pass an examination of medical fitness, he may apply for a Colonial post. The salary commences (as a rule) at £300, increasing by annual advances of £10 to the sum of £400 per annum. In some cases there are special transit and other allowances, while private practice is permitted so long as it does not prevent the due performance of official duties. Then there is, of course, the further important condition of the ultimate eligibility for pension in accordance with service rules. The suitability of such appointments must always be more or less determined by the temperament of the individual applicant. The great advances in the scientific knowledge of tropical diseases and the present high standard of medical education have added vastly to the attractions of Colonial medical posts in recent years. Those who are likely to entertain the idea of following such a career can obtain full details of all appointments of the kind by applying to the Medical Department of the Colonial Office.

A "New Remedy" for Consumption.

THE *Morning Advertiser* of the 10th ult. announced a new discovery by a "scientist" named A. V. St. Armande, residing at Southend-on-Sea. The remedial agent is a gas which, when inhaled, has the power of suspending ordinary sensation, without interfering with the senses of hearing and speaking. He would be a bold man indeed who would declare the impossibility of the existence of a gas having those curious properties! At the same time it seems more than likely that the news of so remarkable a discovery would have wakened the echoes of the medical world in London and elsewhere. Such a claim is capable of proof or of disproof, and is of such importance to the community that it deserves to be put forthwith to an authoritative test. That remark applies with a thousandfold increase of weight to the further claim of the talented inventor that his gas cures consumption (presumably of the lungs), as well as lupus. Were that the case it would become the bounden duty of the State to secure this marvellous weapon against tuberculosis. If Mr. St. Armande wishes to have his gas tested upon consumptive patients, and can furnish sufficient grounds for the faith that in him lies, we fancy there will be little difficulty in submitting the matter to accurate scientific examination by expert investigators.

Tuberculosis and the Irish Government.

A deputation representative of the chief medical organisations in Ireland and the leading societies concerned in the suppression of tuberculosis, waited on the Lord Lieutenant last week at Dublin Castle for the purpose of urging on the attention of the Irish Government certain points on which legislation is sought. The deputation was introduced by the Countess of Aberdeen, and among the members who spoke were the Presidents of the Royal Colleges, of the Irish Medical Association, and of the Ulster Medical Society. Action was demanded from the Government in four directions—the rendering notification of tuberculosis compulsory, the adoption of more stringent measures for the control of milk and food supplies, the granting of power to the county councils to erect and maintain sanatoria and dispensaries, and the inauguration of a proper system for the inspection of schools. No one who knows anything of the condition of Ireland as regards sanitary matters can doubt that reform in all these directions is urgently needed. In all of them Ireland lags far behind the rest of the kingdom, and, as a result, the mortality from tuberculosis is much higher than elsewhere. As was to be expected, the deputation received a sympathetic hearing from the Lord Lieutenant, the Chief Secretary, and the Vice-President of the Department of Agriculture. Mr. Birrell promised that the Government would do its best to give effect to the representations of the deputation as early as possible, and perhaps it was impossible for him to be any more definite. Mr. Russell, however, was able to make a definite statement of much importance, though only touching on one of the points raised. He said that in the County Wexford, under the Department of Agriculture, there was being carried out a system of veterinary inspection, by which it was proposed to apply the principle of the Medical Charities Act to the diseases of animals. If the experiment succeeded in Wexford, there was no reason why it might not be applied in other counties. We trust that no opportunity may be lost of forcing the serious points raised on the attention of the Government.

Dirty Dublin.

In a speech the other day at the inauguration of the Dublin Branch of the Women's National Health Society of Ireland, the Dean of St. Patrick's very properly referred to the dirty condition of the streets of Dublin, and the evil influence of that condition on the health of the citizens. Without the excuse of thick smoke or heavy fogs, Dublin is without doubt one of the most dirty cities in the kingdom. No feature of the city so strikes a stranger, or a resident after a period of absence, on entering Dublin, as the uncleansed condition of the streets. In many of the Continental cities, and in London and the great cities of England, men or boys are constantly employed in keeping the streets clean. Horse-droppings are immediately removed with brush and shovel and no refuse is permitted to lie in the street. In Dublin no attention is paid to matters of the sort. Horse-droppings, scraps of paper, garbage of all sorts, and mud of the streets, are beaten together by wheels and feet till after nightfall, when the streets may or may not be swept, and the sweepings may or may not be carted away. In dry weather the same sweeping-machine is used, without any previous watering of the streets, with the result that dust is blown in eddies to the bedroom windows, carrying indescribable filth to the lungs of any sleepers who may leave their windows open. It is as a result of the carelessness shown by the sanitary authorities in such matters as this, that Dublin retains its position as one of the most unhealthy cities in Europe.

Florence Nightingale, O.M.

The raising of Florence Nightingale to the Order of Merit has awakened as much pleasure as surprise in the country, for though she is old, indeed nearly ninety, the memory of her heroism and goodness still shines brightly in every British home. We venture to think that there is no other woman whose appointment to the Order could have passed without challenge, but every paper in the land has nothing but praise and congratulation for Miss Nightingale's inclusion. To ourselves it is a particular pleasure and privilege to add our tribute to those already bestowed on the venerable lady, who, already enshrined as a saint in America, in this country is in actuality, if not by canonisation, the patron saint of modern nursing. Florence Nightingale's career is one of such peculiar beauty and merit that it awakens good in all who contemplate it. In all her struggles and official combats she never forgot her womanliness, and her capacity as an organiser was never allowed to obscure the fact that she was a true, tender-hearted nurse. There was nothing of the arm-chair sentimentalist about her, but she was always a living and practical power. When we consider how "honours" are bestowed, we should have resented at most any of the ordinary distinctions being conferred on Miss Nightingale, but to have placed her in the Order of Merit shows on the part of the Prime Minister an appreciation of the fitness of things which is wonderfully to his credit. That Miss Nightingale may long be spared to wear her insignia, and that her place among the immortals may help to keep green the memory of her goodness, we most heartily wish.

Spurious Sports.

It were well for those who love the lower animals to divert their attention from experimental researches, which are conducted in the highest spirit of altruistic science, to the horrors that are daily committed upon the brute creation merely to satisfy the lust of sport. The sentimentalists who cut such a sorry figure over the "Little Brown Dog of Battersea," and the monumental record of a failure to prove their statements when tested in a British court of law, will find abundance of maimed lower animal life in the shape of rabbits, deer, pigeons, and so on, to perpetuate in bronze and marble. Let them lay to heart the following resolution framed recently by the Royal Society for the Prevention of Cruelty to Animals:—"That this meeting," it ran, "representing branches of the R.S.P.C.A., kindred organisations for preventing cruelty to animals, ethical and other societies, and individuals of various schools of thought, desires to record its strong conviction that the time has come when certain spurious sports, to wit, the hunting of carted deer, the coursing of captured rabbits, and the shooting of birds from traps, should be forbidden by law, as being not only wantonly cruel to the animals thus hunted, coursed, or shot, under wholly artificial conditions, but also demoralising to those who practise or witness such things; and appeals to his Majesty's Government to grant facilities in the coming Session for a discussion of the Spurious Sports Bill, which would render these degrading pastimes illegal." The Hon. Stephen Coleridge, in supporting the resolution, was careful to point out that it was absurd to say they were not to put down one kind of cruelty until they had put down all kinds. But why does not Mr. Coleridge, so to speak, begin at home, that is to say, with cruelty committed for the sake of sport, of personal decoration, and in mere wantonness of slaughter?

The People and the Hospitals.

The continuous readjustment of our social relations is a necessary consequence of the laws that govern the evolution of society. Where from any cause the gradual changes attendant on such a process are arrested, things are apt to right themselves in the disastrous upheaval that is termed a revolution. Fortunately, a crisis of that kind seems foreign to the British genius and temperament, in spite of the political agitation that has recently been raised against Socialism and all its works. As a matter of fact, there is a good or Christian socialism, and a bad or nihilistic socialism, which require to be carefully distinguished. But every member of the poorer classes of the community, whatever his political or his social creed, must reckon with the enormous amount of money directly and voluntarily given by the wealthier classes to the medical charities. Incidentally a corresponding amount of gratitude is due to the medical profession, which provides gratuitous service to the hospitals. The extent of the benefaction may be estimated from the statement that in London alone one out of every three or four of its inhabitants resorts to those institutions in the course of each year. In some socialistic quarters it is the fashion to clamour for public supervision of these privately-subscribed funds. On general grounds there is no particular reason why a well-devised central control of some kind should not be instituted. Indeed, to a partial extent, the principle is being enforced by the various Hospital Funds of the United Kingdom.

PERSONAL.

Miss **Florence Nightingale** has been gazetted to the Order of Merit by the King. Miss Nightingale is the first woman to receive the distinction.

Princess Christian, president of the Liverpool School of Tropical Medicine, paid a private visit to the school on November 27th, and was conducted over each department by the various heads.

Dr. George Williamson has been elected President of the Aberdeen Medico-Chirurgical Society.

Mr. Haffkine, C.I.E., has been offered and has accepted an appointment under the Indian Government.

Dr. Edwin Bramwell, son of Dr. Byrom Bramwell, has been elected Assistant Physician to the Edinburgh Royal Infirmary.

Dr. G. W. Watson has been appointed Physician to the Leeds Public Dispensary, in succession to Dr. Wardrop Griffith, appointed Consulting Physician.

It is said that the Nobel Prize of £8,000 is to be awarded to Professor Laveran in recognition of his studies on Paludism.

Professor Wright, M.Sc., of Leeds, has had the title of Emeritus Professor of Midwifery conferred on him on his resignation of the active chair in that subject.

Professor John Ferguson, M.A., LL.D., will preside at the Glasgow University annual dinner at the Trocadero Restaurant, W., on Friday, December 6th, at 7.30 p.m.

The Bradshaw Lecture of the Royal College of Surgeons of England will be delivered by Rickman J. Godlee, Esq., M.S., F.R.C.S., on Friday, December 6th, at 5 o'clock.

Colonel G. D. Bourke, C.B., R.A.M.C., has been selected to succeed Surgeon-General J. D. Edge, C.B., R.A.M.C., as principal Medical Officer of the Irish Command next May.

Dr. Abraham Ellenbogen has been presented by the B. Division of the Liverpool police with an illuminated address in recognition of his professional skill in saving the life of a badly wounded constable.

A statement that was published to the effect that the King would probably visit West Wales at Eastertide to open the Alltymynydd Consumption Sanatorium is unfounded. Princess Christian will probably perform the ceremony.

Mr. Jameson Evans, Surgeon to the Birmingham and Midland Eye Hospital, will deliver the Richard Middlemore Post-Graduate Lecture for 1907 at that hospital on December 12th, at 4.30 p.m. The subject is "The Prophylactic Measures in Ophthalmology."

Mr. John Murray, F.R.C.S., has been appointed surgeon, and Mr. Gordon Taylor, M.A., B.Sc., M.B., M.S., F.R.C.S., has been appointed assistant surgeon to Middlesex Hospital, vice Mr. Andrew Clark, F.R.C.S., who has resigned on account of ill health.

Mr. Thomas Donovan, a member of the Cork Municipal Corporation, has undertaken that if, during the coming session of Parliament, a Bill is passed creating the Queen's College, Cork, a University for the South of Ireland, he will contribute towards its funds the sum of £1,000.

The Arnott Memorial Medal has been awarded by the Irish Medical Schools and Graduates Association to Sir R. Havelock Charles, Physician-in-Ordinary to the Prince of Wales, in recognition of the great advances he made in the technique of the surgical treatment of certain endemic diseases in India.

Mr. Chamberlain has received the following telegram:—"We, as president and chairman of the Liverpool School of Tropical Medicine, desire, on behalf of the school, to ask your acceptance of the Mary Kingsley medal, founded by the school in memory of the late Mary Kingsley for presentation to those who have specially distinguished themselves in the noble cause of the amelioration of health conditions in the tropics—a cause which you personally have so much helped.—Princess Christian of Schleswig-Holstein, President; Alfred Jones, Chairman."

A Clinical Lecture

ON

EXOPHTHALMIC GOITRE AND MYXŒDEMA. (a)

By R. W. PHILIP, M.A., M.D., F.R.C.P., F.R.S.E.,

Physician and Lecturer on Clinical Medicine, Royal Infirmary, Edinburgh.

Gentlemen,—I propose to-day to ask your attention to two cases which have a certain etiological and clinical relationship, and which present certain remarkable contrasts. The first is a case of exophthalmic goitre, and the second is one of myxœdema. Both cases are highly illustrative, not merely of the main features of these diseases, but of certain aberrations from the more typical clinical type. As you are aware, the prevailing view at present is to regard these two diseases as expressions of two different aspects of disturbance of the function of the thyroid gland.

Without going into minute details, it is sufficient for our present purpose to recall that the thyroid gland seems to have, as one of its functions at least, the elaboration and secretion into the blood-stream of a certain substance necessary for healthy metabolism. I shall not stay at this point to discuss with you the nature of that substance, or its exact action in the normal subject. Apparently the amount of the substance elaborated and secreted is most carefully regulated by some mechanism about which we can only theorise. Certain it is that from time to time disturbance in this finely adjusted arrangement takes place. This may be in one of two directions. Either an excess of the substance is allowed to pass into the blood—whether from over-elaboration or extra secretion we need not discuss for the moment—or, on the other hand, too little of the substance is supplied. In the one instance we have the condition which may be described in a word as hyperthyrea, and in the other we have the condition which may be described as athyrea (or hypothyrea). Returning to the two cases before us, there is considerable reason for regarding exophthalmic goitre as essentially a condition of hyperthyrea, and myxœdema as essentially a condition of athyrea.

With this general introduction we may pass to a short account of the history and leading symptoms of the individual cases.

Case I.—Mrs. H., æt. 47, a seamstress, was admitted to Ward 33 on September 27th. Her chief complaint was projection of the eyeballs, nervousness and general weakness.

History.—About 10 years ago the patient suffered from severe nervous shock. Owing to domestic disturbance, she was suddenly subjected to intense worry and to quite unwonted strain in the way of work. For two or three years, apparently, she worked the greater part of day and night, four days a week. Two years after the advent of the severe shock, it was noticed that her right eye seemed to project unusually. About a month later the patient noticed her throat to be "swollen," as she puts it, and she began to be troubled with palpitation, at first on exertion, and then latterly from very slight cause. She became so nervous that when the bell rang she was unable to open the door. On a number of occasions she had fainting turns, either complete or partial. From time to time a feeling of grave dread seized her which quite unnerved her. Throughout this period the projection of the eyes became more definite. This continued to be more marked on the right side, but the left came to project almost to the same extent. There was a gradual advance of symptoms during the eight years referred to, with alternating periods of remission and subsequent exacerbation of symptoms. About three months ago—the date corresponding approximately with the onset of the climacteric—she became rapidly worse. The nervousness got extreme, and on one occasion she fell down in the street, believing that she was dead. Of previous illnesses, we may note that 10 years ago she was operated on for an ovarian tumour, which was removed. A year or so later she had an illness of six weeks standing, which is described as rheumatic fever. She has had other rheumatic manifestations. She had pleurisy, with effusion, 10 months ago, and apparently congestion of the lungs when she was a child. In the family history there is little of importance. She has one son, alive and well. One child was born prematurely at five months. There have been no miscarriages.

In the above history I shall ask you to note that the patient, who is now 47 years of age, was at the commencement of her illness rather beyond the age at which exophthalmic goitre is most common—that is, between the twentieth and thirtieth year. As you remember, the disease is more frequent in women than in men. You will note also the precedent rheumatic history. The frequency of this has been emphasised by Robinson and others, who have based thereon treatment by salicylates.

The present case affords a striking example of what seems truly to be the commonest exciting cause of the disease—namely, mental disturbance, worry and depressing influences.

Passing now to her present condition, the most remarkable feature is the exophthalmos. You have doubtless seen examples of the condition before. You probably never have seen it in more extreme degree. It may be convenient to consider to what extent the recognised features of the disease are present in the given case, and to amplify the clinical picture by anything that may be special to the case.

1.—Exophthalmos.

In the present instance this is, as it is most commonly, bi-lateral. It is extreme, and is more pronounced on the right side, which we have just seen was the side first affected. The eyeballs are so projected that one feels as if, on excitement or effort, they might be completely dislocated. There is the characteristic staring aspect, produced, as you know, through the presence of the white ring of sclerotic round the pupil. The upper eyelid is conspicuously retracted, so that the palpebral aperture is much greater than usual (Stellwag's sign). As the patient casts her eye downwards, there is a hesitancy in the downward movement of the upper lid, so that the sclerotic above the pupil is further exposed (Von Graefe's sign). In this particular case, the retraction of the upper eyelid and the projection of the eyeball is so great that the cornea has become inflamed. There has been recurrent keratitis and ulceration of the cornea. Closure of the lids at night is not quite complete, so that special measures have had to be taken to protect the eyeball. There is interference with the natural convergence of the eyeballs (Moebius' sign). Accommodation is undisturbed, and there is no interference with sight. The pupils and the optic nerve seem natural.

2.—Thyroid Enlargement.

This is not very conspicuous. There is, however, some general enlargement of the organ. The right lobe is rather more affected. The swelling is soft and elastic to the touch. There is no marked thrill, and only a slight systolic bruit on auscultation. The patient reports that the enlargement of the gland was considerably more at one time.

[(a) Delivered in the Royal Infirmary, Edinburgh, Nov. 8th, 1907.]

3.—CIRCULATORY DISTURBANCE.

This is marked. Palpitation, dyspnœa, and tendency to faint have been conspicuous, more especially on exertion or excitement. There has also been some swelling of the feet. The pulse rate on admission was 128, and has varied from that to 92 yesterday. The pulse is of medium size. At first the systolic pressure was conspicuously high, reaching as much as 210 mm. Hg. (Riva-Rocci's sphygmomanometer). There is more or less arterial throbbing. The heart's action is quick, forcible and rather diffuse. Auscultation reveals the presence of a systolic murmur, heard especially in the mitral area and propagated towards the axilla.

4.—NEURO-MUSCULAR PHENOMENA.

The patient is very nervous and excitable. On this account I have kept her quietly in a side ward. Fine muscular tremors are observable in the hands and fore-arms. As compared with many such sufferers, the patient is not thin. Indeed, her general condition externally would attract little remark. She is not conspicuously pallid, nor is there much evidence of pigmentation. Flushing of the skin occurs readily, and generally the skin feels rather moist. The appetite is good, and digestion is natural. Patient's intelligence is quick, and the other cerebral functions appear normal.

Before we pass to Case II., I should like to read to you the earliest description of exophthalmic goitre which occurs in literature—I mean that by Dr. Caleb Hillier Parry, of Bath. It occurs in his posthumous works, published in 1825. The observations were made much earlier. He draws attention to the coincidence of enlargement of the thyroid gland with enlargement and palpitation of the heart, and proceeds to give illustrative cases as follows:—

"The first case of this coincidence which I witnessed was that of Grace B., a married woman, æt. 37, in the month of August, 1786. Six years before this period she caught cold in lying-in, and for a month suffered under a very acute rheumatic fever, subsequently to which she became subject to more or less of palpitation of the heart, very much augmented by bodily exercise, and gradually increasing in force and frequency till my attendance, when it was so vehement that each systole of the heart shook the whole thorax. Her pulse was 156 in a minute, very full and hard, alike in both wrists, irregular as to strength, and intermitting at least once in six beats. She had no cough, tendency to faintness, or blueness of the skin, but had twice or thrice been seized in the night with a sense of constriction and difficulty of breathing, which was attended with a spitting of a small quantity of blood. She described herself also as having frequent and violent stitches of pain about the lower part of the sternum.

"About three months after lying-in, while she was suckling her child, a lump of about the size of a walnut was perceived on the right side of her neck. This continued to enlarge till the period of my attendance, when it occupied both sides of her neck, so as to have reached an enormous size, projecting forwards before the margin of the lower jaw. The part swollen was the thyroid gland. The carotid arteries on each side were greatly distended; the eyes were protruded from their sockets, and the countenance exhibited an appearance of agitation and distress, especially on any muscular exertion, which I have rarely seen equalled. She suffered no pain in her head, but was frequently affected with giddiness."

Could you wish, gentlemen, for any more vivid description? And, mark you, the record is of a case seen fifty years before Graves or Basedow wrote of the disease. It is curious to find that both these names have become associated closely with it, while if any name deserves to be kept in memory in relation to exophthalmic goitre, most certainly it is that of Caleb Hillier Parry.

CASE II.—Mrs. M., æt. 40, keeps her own house, was admitted to Ward 33 on October 16th. Her chief complaint was general swelling, which had been increasing for some years.

History.—Six years ago, shortly after the birth of her last child, the patient noticed that she was getting stouter. Her clothes felt tight and small, and her friends remarked that she was getting bigger-looking. The swelling gradually increased, affecting the whole body—face, arms and legs, as well as the trunk. She was not only fatter, but there was a feeling of stiffness in the skin. She noticed about the same time that her hair was becoming dry and brittle, and fell out. She experienced advancing weakness and disinclination for physical and mental effort, shortness of breath and headache. Her memory, which previously had been excellent, tended to fail. She found that she forgot things easily which previously she could not have failed to remember. From time to time she found herself stopping in conversation because she seemed to have forgotten what she wished to say. There is little in the previous history of importance. For the last 20 years she has had no serious illness. The family history is similarly satisfactory. There is no history of tuberculosis. There has been some slight rheumatic tendency. She has had nine children, all of whom are alive and well. There have been two miscarriages, respectively four and two years ago. She has always been in comfortable circumstances. Perhaps the most noteworthy point in the history concerns her reproductive activity. She is only 40 years of age, and has had 11 pregnancies. Frequency of pregnancy has been cited as a determining influence by some observers.

As to her present condition, certain of the features are less striking than they were ten days ago, for the reason that the patient has been undergoing special treatment, to which I shall refer presently. The appearances are, however, characteristic. The face is conspicuously broad and expressionless, and the neck and shoulders much thickened. Similarly the hands are swollen and broadened. The fingers have lost their expression, and have become uniformly thick. The whole hand has what has been described as a "spade-like" aspect. These remarks apply also generally to the feet. The cutaneous tissues have a firm resistant character. There is no pitting on pressure. The skin of the face is pallid and rather yellow, with a bright red spot in the malar region. The lips, which are rosy, have a distinctly livid tinge. The skin is markedly dry and harsh. Perspiration is wanting. The hair is dry and brittle, and has a coarse aspect, and, as you have heard, has been falling out. The nails show nothing unusual. The teeth have almost all gone through caries. The thyroid gland is small and hardly determinable. The appetite is poor. The tongue is remarkably large.

The expression of the patient is dull and heavy; a fortnight ago it was very much more so. The patient has the strange consciousness of being stiff. Mental activity similarly is languid. Memory is certainly defective. The speech is not conspicuously disturbed. The urine contained .218 gr. albumin per ounce on admission, but this has disappeared. The mean pulse rate during three weeks has been 84. The temperature has ranged from 96.3° to 98°. The patient feels cold readily.

If we rehearse, then, the leading points in relation to these cases, the remarkable contrast strikes us at once. In Case No. I., there is the highly nervous, sensitive, almost irritable aspect, with the staring gaze from the widely separated lids and protruding eyeballs. In the other case there is the ultra-placid, even dull and lethargic aspect, with the heavy look about the eyes, which are seemingly deep-set behind heavy, thickened eyelids. In No. 1, the whole neuro-muscular system seems in a state of flux and vibration, while in the other case the tissues seem fixed as in a gelatine cast, which renders impossible all finer vibratory movement. And what applies to the external aspects of the patients applies similarly to so-called intellectual motions. There is no need to elaborate this point further. It is evident from all we have seen. Then in Case No. I., there is enlargement of the thyroid gland, less, it is true, than often in such cases, but still definite. In the other case the thyroid gland is hardly, if at all, determinable. Lastly, in the first case the circulation is rapid, full and excitable, the skin surfaces are warm and moist, while in the other case the circulation is sluggish, superficial surfaces are cold, dry, harsh, and the cutaneous appendages in a state of low vitality.

So much for points of contrast. The common meeting-ground for the two cases is the thyroid gland. In both cases there is evident disturbance in size, though in opposite directions, and we have abundant reason to say disturbance in function also. In the first case the gland is much enlarged, and as histological examination shows, is in a state of active proliferation, with corresponding increase of functional activity. In the other case, the gland is in a state of partial, or maybe complete, atrophy, with corresponding reduction in functional value. This common meeting-ground, with the two opposing aspects of excessive activity (hyperthyrea) and reduced activity (athyrea), affords the basis for the now generally accepted line of treatment in the two cases.

In myxœdema (athyrea), of which Case No. II. is a good illustration, the therapeutic indication is to endeavour to compensate for the insufficient activity of the thyroid gland by the introduction of thyroid extract, obtained artificially from another animal. The procedure first proposed by Horsley and Murray is now so generally accepted that I need not dwell on the matter in detail. Liquid and solid extracts are obtained from the thyroid of the sheep, and are administered subcutaneously or by the mouth. In ordinary cases we make use of thyroid feeding, and commence with 1 to 5 gr. of the solid thyroid extract, three times a day. In the present instance the patient, after a fortnight's observation, received 5 gr. of the extract thrice daily. She has had this for nine days, with the remarkable result that already her aspect is much more natural, her expression more lively, her mental activities keener, and she has dropped 7½ lbs. (a) —that is, almost 1 lb. per diem. In addition to this, the albumin has quite disappeared from the urine, and the hair has assumed a more natural appearance.

On the other hand, in exophthalmic goitre, of which Case No. I. is so striking an example, many lines of procedure have been suggested. Restricting ourselves, however, to-day to its dependence on thyroidal disturbance, the question arises how we are best to meet this? In the foreground we may exclude the use of thyroid extract which has been actually proposed. I say we may exclude the use of thyroid extract as likely rather to intensify than to improve the symptoms. By a curious paradox, however, benefit appears to have followed its use in some cases. In this connection I may remind you that sometimes myxœdema follows on exophthalmic goitre. It is conceivable that for such transitional cases thyroid extract should prove serviceable. Still, exophthalmic goitre recalls so definitely in various ways the effects produced by over-dosage with thyroid extract that it seems undesirable to proceed in most cases to treat exophthalmic goitre in this fashion.

The assumption has been made, however, that, in the condition of myxœdema which is so remarkably benefited by the exhibition of thyroid extract, there must be present in the circulation some product which is opposed to and neutralised by thyroid extract. If, then, myxœdema be artificially induced in an animal, say the goat—that is to say, if the thyroid gland be removed and the condition known as cachexia strumipriva be established, there is produced within the circulating blood a certain quantity of this principle, antagonistic in action to the thyroid secretion. If, then, the serum of such an animal be removed and administered to the patient suffering from hyperthyrea—excess of thyroidal secretion—the assumption is that the latter is antagonised, and once more a state of equilibrium restored. Such a serum has been prepared under the direction of Moebius, to whom I have already referred, and is known as "antithyroid serum" (Moebius). It is exhibited in doses of from 10 to 60 minims, and is conveniently given in milk, or it may be in wine.

This treatment was commenced eight days ago in Case No. I., after the patient had been treated for five or six weeks on the older lines of rest and cardiac and other tonics. We began with 10 minims of the antithyroid serum twice daily, and the dose is being gradually increased. In the interval a certain improvement has been noticed, both by us and the patient herself. It remains to be seen to what extent the effects are traceable to the treatment, and whether they are progressive. Perhaps on some future occasion I may have the opportunity of referring to this point. It seems to me that much may be said for the plan, both from the theoretical point of view and practically from results I have obtained by the method in more than one case already. The results, both in my own hands and in those of other observers, have, however, not been constant. We must admit that the method is still on trial.

The two cases I have presented to you to-day afford, then, a particularly interesting study, not merely in relation to their clinical features and pathological relationships, but also in respect of their scientific treatment. I would have you note, however, that in thus considering the two diseases in relation to the thyroid gland, we are still far from an exhaustive conception, either of their pathology or their treatment.

Admitting that a certain number of symptoms occur together with sufficient regularity to justify their being grouped as a distinct disease, which we call, on the one hand, exophthalmic goitre, and on the other myxœdema, we are still at sea regarding the ultimate cause of the mechanism of production. The history of many cases of exophthalmic goitre points to the nervous system as the primary seat of disturbance. The disease would thus seem to be traumatic in origin, using that term in a wide sense. The subsequent steps in causation still require elucidation. Even the order of clinical events is different in different cases. Murray's statistics indicate that, in the majority of instances, the first morbid appearance is to be found in the thyroid gland, which becomes enlarged. Later, it may be years after, the circulatory excitement appears, and then still later the exophthalmos, and the more general neuro-muscular disturbance. I need hardly remind you that even if this order of events be accepted as the more frequent one, the traumatic origin of the disease—that is, the relation of the disease to nerve-shock—is in no wise prejudiced.

There are probably other channels through which the disturbance of the thyroid gland is produced and maintained, as in the case of other organs. While the more evident clinical manifestation is more or less uniform, there may be considerable diversity of causation. Such diversity of causation may, after all, explain the seeming paradoxes to which I have referred in relation to treatment. And what applies to our conception of exophthalmic goitre applies, *mutatis mutandis*, to that of myxœdema.

The treatment which has been proposed for both diseases, so far as we have discussed it to-day, is not, in the true sense, an ultimate one. It is rather a matter of compensation than of cure. Remove the myxœdematous patient from his daily dose of thyroid extract and he steps back quickly into the old state. The process of compensation must be maintained, apparently, in some degree, for the rest of his life. And so, perhaps, in respect of the treatment which we have discussed for exophthalmic goitre.

In a certain way the treatment presents analogy with the treatment of diabetes. We antagonise, we neutralise, we minimise certain morbid manifestations, but in the majority of cases we fail to cure. We want to get still farther behind the scenes, and, if possible, correct the faulty mechanism (disturbed innervation?) on which the defect in the secretory function depends.

It remains for me to make reference to an evident application of treatment which Case No. I. illustrates. Here the protrusion of the eyeball, as we have seen, is so extreme that injury is apt to accrue, not only by day, but also by night, when the eyelids fail to close completely. In the present instance, inflammation and ulceration of the cornea has ensued. To obviate this, it is desirable to arrange a splint of plaster, especially for night use, which passes from the upper edge of the upper eyelid down to the upper level of the malar region. Thereby the eyelids are kept closed.

It has been suggested that in such pronounced cases the proper course to follow is to practise partial enucleation of the thyroid gland. Unfortunately, two difficulties confront us in this connection. In the first place the operation is a serious one. Statistics are less favourable than the patient might desire. Thus Mayo's statistics show that, of 40 patients operated on, 6—that is, 15 per cent.—died as a direct result of the surgical operation, 25 per cent. were partially improved, and 50 per cent. were so much improved that a cure might be spoken of. In the second place, in the patient before us, the thyroid gland is now comparatively little enlarged, and has been getting smaller, while there has been no simultaneous improvement in relation to the exophthalmos. So definite has been the diminution in size of the thyroid, that, taken along with one or two other manifestations in the patient's aspect, etc., the query has passed through my mind whether we may not see realised in this particular case the transition from a case of exophthalmic goitre to one of myxœdema.

(a) Three weeks later she had dropped as much as 21¾ lbs.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Macleod Yearsley, F.R.C.S., Senior Surgeon to the Royal Ear Hospital. Subject: "Otosclerosis."*

ORIGINAL PAPERS.

HIGH FREQUENCY EFFLUVATION AND SPARKING IN THE TREATMENT OF MALIGNANT TUMOURS. (a)

By Dr. J. A. RIVIERE,

Paris.

[Specially Reported for this Journal.]

At the present time, when many eminent surgeons acknowledge the efficacy of physico-therapeutics, I wish again to bring forward the propositions I was the first to assert in 1900 and 1903.

Certainly, in spite of the wavering condition of actual therapeutics, in spite of the fatalism existing in the theories on the obligatory increase of malignant tumours, I deem that the cures (pretty numerous), and the numberless very grave cases in which improvement has been obtained by the aid of physico-therapeutics, should make us regard as culpable negligence the fact that no recourse has been had to these agents which pre-eminently have a local and general modifying effect, all the more so because, when in the hands of experienced medical men, they present no danger and give rise to no inconvenience.

On those lines I wish to bring before this Congress a useful contribution by summing up my observations of more than ten years, and to demonstrate plainly at this meeting the results of my clinical experience.

Amongst the physico-therapeutic agents whose action is the most remarkable, I must, above all, point to high frequency and high tension effluves and sparks. The regulation of their activity is pretty easy, according to the case. I preferably employ the long currents and the bipolar sparks when it is necessary to act on tumours deeply situated, reserving for epitheliomata the monopolar applications. At the International Congress of Medical Electricity and Radiology (Paris, July, 1900), I gave an account of my first successes by this method. I mentioned them again in 1903 in a communication to the Academy of Medicine, the importance of which was supported by numerous observations and by the presentation of several patients.

In these communications, where for the first time in radiology the diagnosis was sustained by a histological examination, I was the first to assert that which has since been confirmed—namely, that the high frequency effluves and sparks cure both superficial and deep malignant tumours; that they destroy the neoplastic masses, whilst they respect the healthy tissues; that their action on lymphoid tumours is most marked; that they should, in conjunction with the Röntgen rays, when employed after operations, serve to prevent recurrence of malignant tumours; that physico-therapy is the one and only resource in cases of inoperable tumours; that the strength of the Röntgen rays can be very great without producing impairment of the tissues; that occasionally the actinodermatitis seems to hasten and to favour the cure; that it is indispensable to push the treatment as far as elimination of the necrosed parts, then to come back to the general circulation; that the neoplastic cell does not derive any benefit from the synergic forces of the healthy cells under the influence of the nervous system; that it is always necessary to pay great attention to the patient's general condition, as well as to the treatment of the local lesion; that in the presence of a disease as tenacious and grave as cancer, the medical man should know how to accommodate the power of the treatment to the resistance of the disease, and so bring judiciously into play all the resources of the physico-therapeutic armamentarium.

Since that period, without abandoning the use of the Röntgen rays, but faithful to my first convictions, I have, within the knowledge of my colleagues, given the first place in treatment to the high-frequency effluves and sparks as being more reliable and more conclusive. However, according to my usual method (which since 1901 I have many times explained to learned societies and also in the Annals of Physicotherapy), I regard as legitimate (and, going still farther, as indispensable) the therapeutical alternation and superposition of the various physico-therapeutic agents in order to obtain a cure. The medical man, dealing with pharmacology, does he not vary, and at the same time bring together, his authoritative or galenic formulæ? The surgeon, always anxious to carry out antiseptic methods, does he not know how to successfully combine the different resources of materia medica so as to multiply the curative action with a minimum of possible inconvenience? In the same way the physico-therapeutic expert should know, when he realises that the action of one of his remedies is exhausted, how to have recourse to another in order to perfect a complete cure. (Here we have a point of observation the explanation of which can be found even in the warfare between the cells.) This cure, thus considered, terminates, even in the most hopeless cases, in a lessening of the pain, in resolution of the tumour, in improvement of the dyscrasic condition, in re-establishment of the nutritive equilibrium. I have not thought it necessary to employ chloroform and the curette, as later on my confrère, Dr. Keating Hart, has done. The apparatus I have used, all differing in their mode of production and in their intensity, are the best and the most powerful made up to the present date, and I have always maintained that the patient can bear without pain the longest effluves and sparking on condition that these last are not too strong. Those high-frequency sparks and effluves, the different productive arrangement of which allow of variations in their application, are the ones which exercise an elective action on the neoplastic cell.

Between the spark and the effluve there only exists a question in degree of concentration in the strength of the high-frequency. The effluve is a spark divided into more or less fine rain-like spray; it is emitted from an electrode bristling with points, whilst on the other hand the spark is given off from one point only. The effluves and the sparks, thanks to the perfected apparatus I have made use of, can be short or long, scarce or in large numbers, fine or dense; for this it is merely necessary to alter the working of the apparatus. An even better plan is to have at one's disposal, as I myself have, several apparatus of different construction. There are various shades of dissimilarity between different sparks and effluves, according to whether they are short, fine, long or dense. The short, warm sparks of great strength are the ones that exercise the thermo-electro-chemical action of which I spoke in 1900. They destroy the neoplastic masses, and their action proceeds from the periphery to the centre. These sparks, which are derived especially from the small solenoid or even from the primary part of the resonator, cause pain. The long sparks and effluves act by percussion, and their effect is deep. Their action from a certain distance is necessary for the disorganisation of the deep neoplastic cells. The short sparks that are taken up by the small solenoid act specially by their ampérage. The long effluves or the sparks taken up by the secondary part of the resonator act, above all, by their voltage, which can attain 300,000 volts, or 600 watts. The strength of the transformators, the capacity of the condensators, the relations of the different capacities when brought face to face, the length and the diameter of the conduction wires, are so many factors which intervene to modify the condition of the sparks and of the effluves.

(a) Read before the French Medical Congress, Paris, Oct. 14-16, 1907.

As I have always pointed out, the origin of cancers is comprised in a direct insufficiency of the nervous system at a determinate point of the economy. At this point soon appear unexpected disorganised cells, wretched waifs that offer a power of resistance absolutely incapable of withstanding the electrical effluves. These last without delay eliminate the neoplasm and at the same time re-establish the nervous influx and the physiological action of the neurons. I may here remark that the elimination is very much more rapid when the cells are denuded, so that the dynamic penetration can operate directly on the very elements of the tumour. The cancer cell is a young cell (even embryonic), containing within itself an inexhausted reserve of the power of evolution. In my thesis (Paris, 1884) I spoke of the force accumulated and condensed in the generative cell, and of the evolutionary force associated with the material (for me the state of condensation of power). Hallion has cleverly put forward the very likely hypothesis that with regard to cancer we have to deal with a cell rejuvenated by abnormal fecundation, and not with a cell that has remained young and that has taken on again (by reason of any application of vis a tergo) an evolution which for a long period had been interrupted. This is the karyogamic theory, a rational hypothesis of renovation by conjugation or copulation of fertilising nuclei. This theory explains the injudicious and ill-timed effort taken on by a species of cell held in "subjection" to try to regenerate itself in the same manner as a species of cell which is autonomous or "free." For this reason the neoplastic cell is much weakened in its resistance. It conducts itself as a veritable pathological sperm, a promoter of tumours, inasmuch as this aptitude of conjugation, this karyokinetic particularity, are pathognomonic of malignant tumours. Unconfined and absolutely freed as to its direction, thrown out, as it were, the cell becomes the founder of a liberated tribe which renounces, so to speak, all social compact and ignores its previous obligations with regard to the organism. Therefore, as the nervous system no longer directs it, naturally it has a tendency to exhaustion and atrophy (such is the ephemeral existence of protists). All this I have said before, more than twenty years ago, in my works on nevrarchy and nervism.

The ingenious karyogamic theory (supported by Maupas, Fabre-Domergue, and Hallion) explains to us the rarity of cancer at very advanced age, and the pretty frequent etiological rôle played by traumatism, and especially by frequent irritation, in the ordinary proliferation of malignant tumours. By disturbing elementary nutrition we always realise these conditions of imperfect alimentation which, according to Maupas, favour cellular conjugation in the infusoria. I will add that uric acid should also be taken into consideration as a cause of permanent irritation in anatomical elements. It is for this reason that arthritic subjects furnish every day so important a tribute to carcinosis. It is also for this reason that this terrible diathesis presents a development parallel to the curve of the consumption of meat and of fermented or distilled drinks (vegetarians and abstemious people in a large proportion escape the visitation of cancer). High-frequency currents, by preventing the precipitation of urates, by favouring elimination and complete combustion of nitrogenous matter, cut off, as it were, the supplies to the cancerous process, thus preventing the organic cells from taking on karyogamic proliferation, the great abettor of neoplasms and of the most serious neo-organisms.

Conclusions.

(1) It has always seemed to me that high-frequency currents, in the form of effluves or of mono- or bi-polar sparks, enjoy the property of having the most trustworthy, the most continuous, and the most penetrating, modifying action on neoplasms. This observation is the result of experiments and researches lasting over ten years, and my rights of priority in this respect go back to my communication to the Congress of Medical Electrolysis and Radiology (Paris, July 27th, 1900), and to my communication to the Academy of Medicine in 1903.

(2) Nevertheless, one must not be exclusive, and it is our duty to judiciously utilise against neoplasms all the practical agents contained in the physico-therapeutic armamentarium. Röntgen rays, actinism, sparks and currents of static electricity, radium (a), ultra-violet rays, ionisation, electrolysis, etc., etc., all furnish valuable and often indispensable help in hastening the cure either by destroying the neoplastic masses, or by strengthening the neurons, or by impelling the neoplastic particles destroyed and carried away by the stream of the circulation to take on the necessary elimination, or finally by bringing back the vital processes to the normal.

(3) The power of the big bi-polar effluves or of the high-frequency sparks is especially more penetrating and more efficacious in the treatment of deep tumours. It is this power that foils with the greatest vigour the whole histogenesis of malignant tumours, and this without the slightest possible suspicion of inflammatory reaction, inasmuch as violet irradiation contains no calorific ray.

(4) It is the karyogamic theory of Hallion (disordered liberation of the cells and fecundation of the embryogenic elements) that best explains the reason my treatment invariably respects the vitality of healthy tissues, and at the same time possesses a kind of elective affinity for the constitutive elements of the neoplasm.

(5) Malignant tumours from their commencement, recurrent tumours and those considered inoperable, are amenable to physico-therapy.

(6) As in 1900 and 1903, I still persist in asserting that large tumours should be removed by the bistoury and treated afterwards by my method to prevent recurrence, and to cure a recurrence should it take place.

(7) Effluvation and the projection of high-frequency sparks should follow all surgical operations on malignant tumours.

(8) With the object of preventing recurrence after cicatrisation, a few currents applied periodically, then after intervals whose lengths should be decided by a medical man, seem to me of paramount necessity.

(9) Physico-therapy, which is the rational method to employ against malignant tumours, constitutes also for them a line of preventive therapeutics.

GASTROJEJUNOSTOMY AND REGURGITANT VOMITING. (b)

By K. W. MONSARRAT, M.B., F.R.C.S.E.,

Surgeon to the Northern Hospital, Liverpool; Lecturer on Clinical Surgery, University of Liverpool.

It is well known that in a certain number of cases of anterior gastrojejunostomy, and in a lesser number of cases of the posterior operation, the result has proved disappointing owing to the regurgitation of the contents of the duodenum into the stomach. If this co-called vicious circle is established, persistent and exhausting vomiting occurs, and in some instances this has proved the direct cause of death.

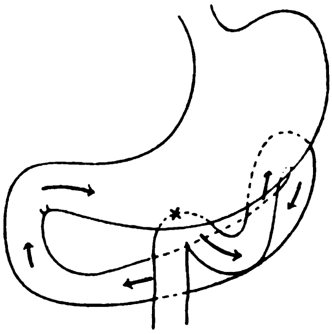
It has been experimentally shown that the mere entrance of bile and pancreatic fluid into the stomach is not capable, in itself, of inducing this complication. It may conceivably arise from one of four mechanical defects left by the operation.

(a) With reference to Radium, it is with much pleasure that I recall a conversation I had with my distinguished colleague, A. Darier, on the occasion of his visiting me in August, 1903, to express his astonishment on finding, when he returned from his holidays, that a patient, who had suffered from generalised lympho-sarcoma, whom he had confided to my care *in extremis* three weeks before, and who had been irremediably condemned by him and by several other medical men, was absolutely cured. I then told him, word for word, that he had before his eyes the result of a combined action of Rontgen rays and high frequency effluves and sparks, that in 1900 I had spoken of the action of the actinic rays, and that, in my opinion, Radium together with actinic and Rontgen rays must have an absolutely certain and positive action on cancer. We went out together to buy some Radium. A little while afterwards, in a very important paper he read to the Academy of Medicine (reported by M. Cornil), he related the case of this patient I had cured by extensive high frequency effluves and sparks and the Rontgen rays, and he seized upon this occasion to speak of the action of Radium on Cancer.

(b) Paper read before the Liverpool Medical Institution.

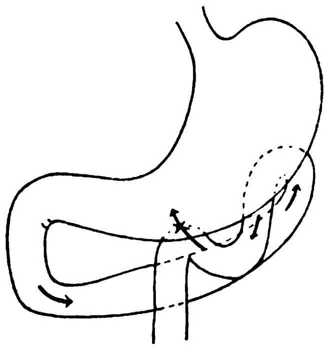
In the first place, the duodenum may empty itself backwards through the pylorus owing to a mechanical obstruction at the point of anastomosis; this is probably the state of affairs in the majority of the cases. Secondly, the duodenal contents may, instead of passing on from afferent loop to afferent loop, empty themselves back into the stomach through the artificial opening. Such an event can only happen, as in the first class, if there is some obstruction preventing the free passage from afferent to efferent loop. Thirdly, the parts may be left in such a situation that the stomach empties itself in the direction of the afferent loop instead of forwards into the efferent branch. Fourthly, an obstruction of the efferent branch may arise, causing it to empty itself backwards into the stomach.

These four types are illustrated in the accompanying diagrams.



It is true that fatal cases have been described by surgeons in which the post-mortem examination showed none of these defects in the mechanical arrangements left by the operation. Still, no other explanations of such cases have been offered, and it is possible that a post-mortem examination might not clearly reveal a sagging afferent loop and an acute bend at the anastomosis which had been present during life to a degree sufficient to cause the complication.

Assuming that in all cases of regurgitant vomiting the explanation is to be found in one or other of these mechanical defects, the method of performing the anastomisis must be so devised that the possibility of their occurrence is avoided.



The characteristics of a satisfactory anastomosis are—

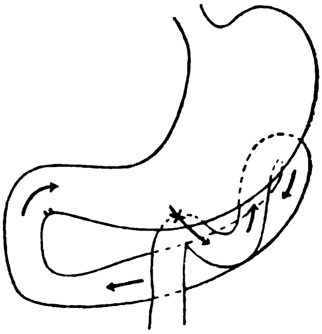
(*a*) An opening large enough to anticipate a certain amount of contraction. The incisions in the stomach and jejunal walls should be not less than two inches in length, and an ellipse of mucous membrane should be removed according to Moynihan's recommendation.

(*b*) A situation at the most dependent point near to the greater curvature of the stomach.

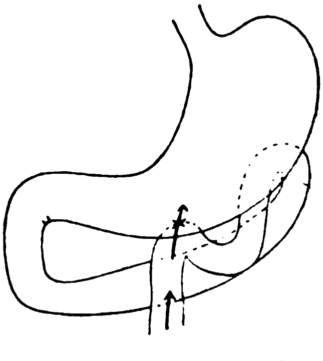
(*c*) A free and unobstructed passage from afferent to efferent loop, and from stomach to efferent loop.

For the avoidance of regurgitant vomiting the third characteristic is all-important, and a whole series of operations have been devised to provide it. (*a*) Kocher's valvular gastroenterostomy is particularly designed to ensure a passage of stomach contents into the efferent loop, and to prevent their passage into the afferent loop. (*b*) The Y-anastomosis of Roux has as its object the certain prevention of the passage of duodenal contents into the stomach through the anastomotic opening. (*c*) The combination of entero-anastomosis with gastrojejunostomy aims at anticipating any obstruction to the passage of the contents of the afferent loop onwards into the efferent loop.

Kocher's method alone without other precautions does not deal with the most common cause of regurgitation, viz., obstruction of the afferent loop at the point of anastomosis. The two other methods mentioned have the disadvantage that they are double anastomoses, and therefore add somewhat to the risk and to the length of the operation.



Petersen was the first to draw attention to a point in the performance of posterior gastroenterostomy which promised to prevent obstruction of the afferent loop at the anastomosis, and therefore to avoid the commonest cause of regurgitant vomiting. He pointed out that the posterior surface of the stomach near the greater curvature and the jejunum near its commencement are, under circumstances of moderate gastric distension, in close relationship with one another, and that these points of normal apposition should be chosen for the anastomosis. The importance of this suggestion has been appreciated by other surgeons. Several advantages follow the establishment of the anastomosis at the point indicated.



In the first place, when the operation is complete there can be no sagging afferent loop to cause a kink at the junction, as, when the parts are returned to the abdomen, the jejunum simply descends from duodeno-jejunal flexure to anastomosis in what is practically a straight line. Secondly, there will be no tendency for stomach contents to collect in the afferent branch; they would have to ascend against gravity to do so.

The results of operation planned on these lines have fulfilled anticipations: It would not be true to speak of regurgitant vomiting as a thing of the past, but now that the anterior operation has been almost abandoned and the posterior operation is carried out in the manner described, it is rarely heard of. During the past year I have paid particular attention to the points in technique which I have mentioned, and though the number of cases in which I have thought gastrojejunostomy indicated is small, I think them worth recording owing to the entirely uneventful course which they have all followed.

Case 2 is of special interest from the point of view of the diagnosis of malignant disease.

1. James R., æt. 29, complaining of epigastric pain and frequent vomiting for about two years, during the greater part of which he had been under medical treatment. He was in a medical ward for a short time before he was transferred, his chief symptom being vomiting of very large quantities of sour-smelling grumous fluid containing lactic and butyric acids and sarcinæ. He was treated by gastric lavage with temporary relief. On examination, the stomach was found dilated so that its lower border reached midway between the umbilicus and pubis; no epigastric tumour was to be felt. Gastroenterostomy was performed on October 4th. There was mechanical obstruction at the pylorus in the form of a thickened indurated area narrowing the channel, evidently a stenosis due to ulcer. He vomited once immediately after the anæsthesia, but not again, and was discharged well on October 30th. He was seen on October 11th, 1906, a year after the operation. He had put on 28 lbs. in weight; the lower border of the stomach was 1½ inch above the umbilicus; he had vomited once or twice during the year, but had had no other gastric troubles.

2. Bridget N., æt. 44. Transferred to my care by my colleague, Dr. Warrington. She had been subject to flatulence and heartburn for a long period, had been vomiting frequently for four months, and had intense epigastric pain. There had been hæmatemesis and also melæna, and she had lost much flesh. On examination, a hard mass was to be felt in the epigastrium about the size of a small orange; forcible peristaltic movements could be seen passing from left to right over the stomach. No free hydrochloric acid was found after a test meal. In the vomited matter there were no sarcinæ, but organic acids were present equal to a total acidity of 50 c.c. decinormal sodium hydrate.

At the operation a large crater-like ulcer was felt on the posterior wall of the stomach at the pylorus; it was adherent posteriorly, where it was surrounded by a hard indurated mass. Posterior gastrojejunostomy was performed. She vomited on the night of the operation, and the following day, and once on the fifth day, but otherwise her convalescence was smooth. She left hospital four weeks after the operation. Seen on October 20th, 1906, seven months after the operation; no abdominal tumour was palpable, she had put on weight considerably, and had no gastric pain or other symptoms. This after-history points to the fact that the epigastric tumour was of an inflammatory nature, although the clinical signs before operation all seemed to point to malignancy. After the operation the perigastritis subsided, and apparently the ulcer healed.

3. Elizabeth M., aged 49. Transferred to me by my colleague, Dr. Bushby. I had previously operated on her for symptoms referable to a movable kidney. There was marked dilatation of the stomach, with splashing and vomiting; the greater curvature reached within three fingers' breadth of the symphysis pubis. There was a distinct hysterical element in the case, which made me hesitate to operate for some time, as the final results in such cases are notoriously uncertain. The point that decided the question was the absence of hydrochloric acid in test-meal experiments. Posterior gastrojejunostomy on July 23rd. The stomach was thoroughly examined, but no lesion suggestive of malignant disease was found. She vomited immediately after the anæsthetic, and once on the eight day after operation, not otherwise. She left hospital seventeen days after operation. Seen four months after operation, she had put on flesh; she still had various complaints in different parts of her anatomy, but her gastric symptoms were at any rate much improved.

4. Thomas C., æt. 43. Sent to me by my colleague, Dr. Warrington. Gastric symptoms for about three years. Pain relieved by food. Had had hæmatemesis on two occasions, and he says also that the motions have often been black. He had lost 4 stone in weight during the previous four months. The stomach extended to half an inch below the umbilicus; frequent forcible and painful contractions of the stomach wall were a marked feature of the case. Hydrochloric acid was present. Operation on July 18th. Duodenal stricture was found, due to cicatrisation of an ulcer. Posterior gastrojejunostomy was performed. There was no vomiting after the anæsthetic or subsequently; previously this had been going on every day. He left hospital twenty-two days after operation in good condition. He has been seen subsequently as an out-patient several times; he put on flesh rapidly, and had no further pain or vomiting.

5. William K., æt. 27. Under medical treatment for eight months for cramp-like pains in the stomach, coming on from half an hour to an hour after food. He improved temporarily, but relapsed whenever treatment was suspended. On examination he presented a marked and localised tenderness just inside the tip of the right costal cartilage; no blood was detected in the stools, but patient described melæna on several occasions. The history and signs pointed to duodenal ulcer. The abdomen was opened on September 26th, and a firm indurated area about the size of a florin, evidently an ulcer, was found in the duodenum close to the pylorus. Posterior gastrojejunostomy was performed. The man vomited once on his return to the ward, not subsequently. His convalescence was retarded by a smart attack of broncho-pneumonia. He left hospital in good condition twenty-four days after the operation. I saw him on November 17th; he had had no further gastric symptoms.

These cases show what an uneventful and even course may be expected when posterior gastrojejunostomy is performed in the manner I have described. Simple suture by means of an inner continuous layer taking up all coats, and an outer continuous layer taking up serous and muscular coats, is the technique to be preferred. Clamps are used for the stomach and the jejunum.

One point has struck me in regard to these and other cases of definite gastric and duodenal ulcer, and that is that in every case the power of mastication has been practically absent owing to wretched teeth. The first step in the treatment of gastric ulcer is to remedy the condition of the mouth. If this is true, physicians and surgeons need not quarrel over the treatment of gastric ulcer in its early stages; it belongs to neither of them, but to the dentist.

OUT-PATIENTS' ROOM.

CHILDREN'S HOSPITAL, PADDINGTON.

Inguinal Hernia in an Infant.—A Simple Truss.

By Arthur Edmunds, M.S., F.R.C.S.

Amongst the out-patients was a male child, æt. 9 months, who was suffering from ordinary oblique inguinal hernia. The swelling was about the size of a walnut, was readily reduced, but reappeared when the child cried or made any other straining effort. The penis was well formed, and the foreskin, although a little long, presented no obstacle to micturition. The child was in all other respects normal; the bowels acted freely and regularly; the appetite was good, and the boy did not cry to any extent except when the hernia was down, when he seemed to experience a certain amount of abdominal pain. The child slept well, the hernia always reducing itself spontaneously during sleep. Mr. Edmunds remarked that these cases are extremely common, several of them being brought for treatment at every out-patient clinique, and their treatment was correspondingly important. For a long time it was taught that operative interference in these cases should be deferred until the child had acquired conscious control over the bladder and rectum, but more recently operations have been undertaken in large numbers and with complete success on these cases. Postponement of the operation is, he said, often disappointing, a child which before had complete control passing his evacuations without any notice after the operation. This, however, is not a matter of such very great moment, inasmuch as it is possible to perform these operations by making the incision rather high up, so that soiling with fæces can be completely avoided. The urine, however, is very likely to soil the dressing, but if the case be carefully watched, and the dressing changed whenever this occurs, disaster is very infrequent. Stiles has attempted to overcome this difficulty by dispensing with a dressing entirely. After the wound has been sutured, it is carefully dried and powdered with boracic acid; a low cradle is then placed over the child, and covered with an old blanket, so arranged that it is only a very short distance above the meatus. The child passes his water directly into this blanket, which is changed as often as necessary. This method is very successful, the resistance to sepsis in a child being sufficient in most cases to overcome the small amount of infection which is introduced through the wound after operation. In this hospital an objection to this type of treatment is the small number of beds at the disposal of the surgeon, so that attempts have to be made to treat these cases as out-patients as far as possible, and this is undertaken with very considerable success. It must be remembered that hernia of this description is produced, not so much by a definite pathological process, as by a delay in the normal physiological one—that is to say, the funicular process remaining unobliterated after birth, so that it is reasonable to hope that if distension of the sac of the peritoneum can be prevented, obliteration will follow in due course. Trusses for children of this age are usually made of india-rubber, a material which can be readily washed, but none the less becomes sodden with urine. As a substitute for this, a skein of wool is extensively used, but it is not very efficient. The best method consists in taking a strip of soft flannel a yard and a half long, and an inch and a half wide. This is folded in two, the folded portion being placed over the neck of the sac, the two tails carried round the pelvis, and ultimately threaded through the loop from above downwards, so as to encircle the body with a noose of flannel. The two ends are then passed under the leg on the affected side and stitched to the belt of flannel at above the level of the posterior superior iliac spine. Attention is now paid to the point where the two tails pass through the loop; there is tendency for the knot produced in this way to wrinkle up, and this must be prevented by spreading out the loop and by stitching its upper corner. In this way a ridge is formed across the inguinal canal, which prevents the hernia from coming down without exercising undue pressure on the delicate structures in this region. Sometimes this truss has a tendency to slip down, and it must then be supported by a shoulder-strap passed across the opposite shoulder. Sometimes there is a little chafing round the groin, but this is usually easily overcome by using a little vaseline. The child is bathed with the truss on, a fresh one being prepared for use after the bath. This treatment must be continued for about 12 months, at the end of which the hernia will usually be found to be permanently cured. This mode of treatment fails in large hernias and in children over 18 months, but for suitable cases it is a cheap and efficient method.

OPERATING THEATRES.

WESTMINSTER HOSPITAL.

Removal of the Rectum and Part of the Sigmoid by the Perineal Route.—Mr. Tubby operated on a woman, æt. 44, who had been admitted suffering from symptoms of intermittent constipation, and a muco-sanguineous discharge from the bowel. She was fairly well nourished, but had a prematurely aged look. The abdomen was moderately distended, particularly in the flanks; she was somewhat tympanitic, but her condition was by no means acute. On examining the rectum, its lower part was found to be distended, but with the finger no sign of growth could be felt, although it was strongly suspected that such was present. Ten days after admission an exploratory operation was carried out, and in the pelvis there could be distinctly felt an irregular hard tumour occupying the lower part of the sigmoid flexure and slightly encroaching on the first piece of the rectum. It was decided to perform an inguinal colotomy, which was accordingly done, the bowel being opened on the second day after the operation. Fæcal matter passed regularly from the colotomy wound, the patient became more comfortable, and her appearance was less emaciated. The question had now to be faced of the best method of dealing with the growth, and naturally the combined or abdomino-perineal method suggested itself. It was, however, finally decided to attack the bowel from the perineum, and, if undue difficulty was encountered to perform an abdominal section and liberate the growth from above. For the past ten days the lower part of the bowel had been washed out through the colotomy wound with boracic acid solution. Fortunately no fæcal matter had passed below the artificial anus, and the boracic acid solution issued from the natural anus slightly stained of a dark brown colour, which originated from breaking down of the growth. With the aid of Messrs. Carling and Swainson excision of the growth was undertaken by Mr. Tubby; it was hoped to preserve the lower part of the rectum with the sphincters, and to be able to draw down a portion of the sigmoid and unite it to the lower part of the rectum. The patient was placed in the lithotomy position with the buttocks well elevated, and good artificial light was provided. An incision was then made from just behind the sphincter ani, then along the median line to the middle of the sacrum. The tissues were rapidly retracted, and the coccyx removed. The levator ani on both sides was detached from the rectum. The finger was then passed up along the hollow of the sacrum, and the bowel detached as high as the sacral promontory. The bowel was also separated laterally and anteriorly from the vagina. It was easy to identify the bowel as it was packed with iodoform gauze. All hæmorrhage having been arrested and the vessels tied, the peritoneum was opened on the right side, then in front of the rectum, then on the left. The growth could now be palpated freely, but at first could only be brought down with difficulty. It was found to have increased greatly in size since the preliminary operation. The main difficulty consisted in the shortness of the meso-rectum and the induration of the lower part of the meso-sigmoid; however, after considerable trouble and very careful detachment of the parts with the finger and forceps, the growth was brought well down and partially outside the wound so that a ligature could be placed rather more than an inch above the tumour. It was found more convenient to begin the removal of the rectum from below; this was accordingly divided between two ligatures about two inches above the anus. The remainder of the rectum, together with the lower part of the sigmoid below the upper ligatures, was then carefully shelled out; it was found to be possible to draw healthy sigmoid down to the remainder of the rectum and join it by a continuous suture. The patient suffered much from shock, as the operation was prolonged, but, happily, Mr. Tubby said, she lost very little blood. The wound was left open, and was fully stuffed with gauze. Mr. Tubby remarked that a preliminary colotomy was of great advantage in these cases, as it not only rendered the patient comfortable, but also permitted the lower part of the bowel to be washed and rendered as aseptic as possible. But it had the disadvantage of causing some difficulties in a subsequent abdominal section on account of the possibility of contamination of the wound. Despite this, in the particular case under notice, he felt that it would have been better to have performed an abdominal section, free the growth from above, and then removed it through the perineum. The shorter duration of the operation and the lessened shock to the patient more than compensated for the risk of sepsis of the abdominal wound. The removal of so large a mass through the perineal route, while showing that a very large portion of the bowel may be removed in this manner, is not, he thought, so satisfactory an operation as the combined abdomino-perineal method.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE

MEDICAL SECTION.

MEETING HELD TUESDAY, NOVEMBER 26TH, 1907.

The President, Dr. S. J. GEE, in the Chair.

Dr. **ALFRED E. RUSSELL** read a paper on the

NATURE OF EPILEPSY.

He said that the old theory that epileptic and many other convulsive attacks were explicable on the hypothesis of a sudden failure of the cerebral circulation was worthy of reconsideration. That such a failure was competent to produce unconsciousness and convulsions had been proved experimentally by several investigators, while the phenomena of Stokes-Adams disease and heart block afforded clinical evidence in the same direction. Opportunities of making observations were scanty because it was impossible to predict when a fit would occur and because the period of cardiac inhibition was of necessity very short. An attack of ordinary syncope (faint) offered both analogies and contrasts to the epileptic fit. Intermediate cases occurred in which it was difficult or impossible to make a diagnosis. The causation of cardiac inhibition in epilepsy must be sought in the marked vaso-motor and cardio-motor instability which was a feature of the disease. Dr. Russell quoted cases in which both vagal and vaso-motor symptoms were combined. The phenomena of *petit mal* were also considered. He observed that the similarity between infantile convulsions and epilepsy was very marked, and submitted that the same explanation held good for them. It was noteworthy that the cardiac and vaso-motor systems in the child were very sensitive, as seen, for instance, in the phenomena of fright. On the hypothesis of cardiac inhibition as the precipitating factor of the fit, recovery followed on the escape of the heart from inhibition. If the hypothesis were correct it should afford a satisfactory explanation of the various phases of the fit, and Dr. Russell submitted that this was the case. In regard to uræmic convulsions, experimental and clinical evidence was brought forward to show that the cerebral manifestations of uræmia might be due to a condition of increased intracranial tension with resulting cerebral anæmia. Concerning Jacksonian epilepsy, the difficulty of correlating cerebral anæmia with this condition was discussed, and evidence was submitted that cerebral anæmia existed both in status epilepticus and in the epileptiform seizures of general paralysis.

Dr. D. **FERRIER** remarked that vaso-motor regulation of the brain circulation was a small part in the consideration of the question; it had been shown that vaso-motor spasm caused flushing of the brain. He did not think there was evidence to show that vaso-constriction would cause anything but flushing. Dr. Russell would transfer the origin of epilepsy from the brain to the heart, but he (Dr. Ferrier) thought they ought to have proof of some definite relation between heart disease and epilepsy, and he did not believe that such proof existed. He quoted figures showing that out of 500 epileptics there were about 1¼ per cent. with some signs of cardiac disease, whereas in 800 cases of heart disease there was not one case of epilepsy. Epilepsy was not so much a matter of the circulation as of the nutrition of the nerve cells. He considered that the condition of the circulation was secondary to the epileptic discharge from the cortical cells.

Dr. C. E. **BEEVOR** said that experimentally by stimulation of the thumb centre it was possible to get a tonic localised contraction, but by using a stronger current it was possible to produce a fit affecting the whole body, and it was certain that in those cases there was not inhibition of the heart. In the case of fits produced by brain tumours, in which it was possible to have fits without loss of consciousness, it seemed impossible that they could be ascribed to want of action of the heart. Those brain tumours might grow and cause fits just like epilepsy, and he did not see how in such cases the heart's action could be taken into account. In regard to *petit mal*, it seemed impossible that the heart failure should have such a limited effect as to produce loss of consciousness, and yet not cause the patient to fall down. Further, attacks of *petit mal* might occur, and be combined with attacks of idiopathic epilepsy. It was difficult to think that the *petit mal* was due to one cause, and the epilepsy to another; they must be due to one cause, and that could hardly be the heart. The question was whether the primary disease was in the heart or in the cortex of the brain, and in his opinion the primary disease was in the cortex, and he did not consider that the heart was responsible in idiopathic epilepsy.

Dr. A. M. **GOSSAGE** said that if cardiac inhibition was to be regarded as the commonest cause of epileptic fits, then there ought to be more evidence of the occurrence of such inhibition than they possessed. He thought it possible that the cases brought forward by Dr. Russell might be classed with cases of Stokes-Adam syndrome.

Dr. J. **LINDSAY STEVEN** (Glasgow) doubted if enough weight had been placed on the factor of vaso-motor anæmia of the brain as a cause of cerebral disease and possibly of epileptic disease. He drew special attention to the relationship that existed between cerebral anæmia and Raynaud's disease.

After Dr. E. **FARQUHAR BUZZARD** and Dr. **BIERNACKI** had spoken, Dr. **RUSSELL** replied, and the meeting terminated.

ELECTRO-THERAPEUTICAL SECTION.

The annual conversazione and exhibition of new apparatus, heretofore held under the auspices of the late British Electro-Therapeutic Society, but now under the Electro-Therapeutical Section of the Royal Society of Medicine, will be held in the Queen's (small) Hall, on Friday, December 13th, 1907, from 7.30 p.m. to 11 p.m. The exhibition will be open from 3 p.m., and light refreshments will be provided both afternoon and evening. All the leading makers of electro-medical and

X-ray apparatus are taking part, and many new designs will be shown, as far as possible under working conditions. A noteworthy feature will be a display of X-ray tubes from the earliest to the latest patterns. Medical practitioners will be welcome on presentation of their visiting cards, as also will members of the dental profession and recognised teachers of the physical sciences. Others will be admitted on payment of a fee of 5s.

Communications regarding cards of admission or other matters must be addressed to Reginald Morton, M.D., Hon. Secretary, 22, Queen Anne Street, Cavendish Square, London, W.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, NOVEMBER 15TH, 1907.

The President, E. H. TWEEDY, M.D., in the Chair.

EXHIBITS.

DR. **ALFRED SMITH** exhibited two fibro-myomatous uteri with ovarian cyst attached. One generally associated with fibroid tumours of the uterus, he said, certain degenerations of the ovary, but he did not think he had seen—certainly not in two consecutive cases like those exhibited—ovarian cystomas associated with fibroid tumour.

The **PRESIDENT** said there was no reason why a cyst should not grow in a woman who was already afflicted with myoma, yet he did not remember ever having seen them attached before.

Dr. **PUREFOY** said that a few weeks ago he had removed a dermoid cyst, with which was associated a fibroid uterus.

On the suggestion of Dr. **ROWLETTE**, one of the tumours exhibited by Dr. Alfred Smith was opened, and proved to be a dermoid cyst.

Sir A. V. **MACAN** exhibited a case of uterine carcinoma and double ovarian cystoma. He said the woman was 45 years of age, had been married since she was 15, but had had no children. The catamenia were still regular, and, except for violent hæmorrhages, the patient complained of nothing. On opening the abdomen an ovarian tumour was found and removed, and, to his surprise, he then found another. The uterus was then extirpated. Afterwards the patient got bronchitis, which gave him some anxiety, and later, out of one of the stitches, fluid stuff came like the contents of a dermoid cyst. However, she made a good recovery.

The **PRESIDENT** thought it was rather fortunate for a woman who was suffering from carcinoma to get an ovarian cyst, as it might cause the diagnosis of carcinoma to be made all the earlier.

Sir A. V. **MACAN**, replying to a question by the President, said the patient was first curetted to make the diagnosis, and it being determined that it was carcinoma of the uterus, it came to be a question of extirpation by the vagina or the abdominal route.

Sir **WILLIAM SMYLY** exhibited a case of sarcoma of the uterus (?), and regretted the note of interrogation, but it was difficult to say what organ the tumour really sprang from. On October 21st he had seen the patient for the first time. She was feverish, and looked very ill. On making a bi-manual examination, he found a myomatous uterus, and also a detached tumour in the abdomen. When admitted afterwards to hospital she had all the symptoms of septic fever. It was quite evident that one of the tumours was suppurating or sloughing, and that she could not live any length of time in her then condition. As a desperate resource he determined to try to extirpate the source of infection. It was generally admitted that it was better to remove a septic tumour by the vagina, as it was less likely to cause a general peritonitis or a hernia than removal by the abdominal route. The woman was unmarried, and had a narrow vagina, which presented the ordinary difficulties. After a good deal of labour morcellating the uterus he got it outside the vulva. It had been held by the tumour above, which had prevented it from coming down. To get the tumour he had, after all, to open the abdomen, and he found everything matted together. He separated the adhesions, scooped out the sloughing *débris*, and left a cavity with ragged, infiltrated walls communicating with the lumen of the gut by an opening as large as a sixpence. It was evident that the malignant disease had extended from the tumour through the walls of the intestines, and it had involved so many of the coils of intestines that he now reached the climax of his woes, and found it impossible to remove the disease. In the desperate circumstances he stitched the intestines round the cavity as well as he could, and the woman had not exhibited any bad symptoms up to that day, which was the fourteenth from the operation.

Dr. **HARVEY** confirmed Sir William Smyly's remarks as to the difficulty of saying what the tumour really was. Histologically it was mixed-celled sarcoma.

PRESIDENT'S ADDRESS.

Dr. **HASTINGS TWEEDY**, in thanking the section for electing him their President, said that the position had been held in the past by men who had made the Obstetric School of Dublin famous, and that it was through the Royal Academy of Medicine in Ireland that the profession in Dublin have the opportunity of making known to their countrymen and to the world at large that their work is worthy of more than provincial fame. He complained that the section had not of late years received the support it deserved, and it lacked the vitality of the past. This slackening of interest dated from about the beginning of the Boer War, and in his opinion might be attributed to it. The war had a most disturbing influence on men's minds, and during a period of almost daily disaster the members of this section had no heart to attend the meetings; thus habits were formed of which the influence is still felt. Of other explanations, the most plausible is that which suggests that gynæcology has ceased in its power to interest, and that as an art it has made no appreciable advance within the last decade. In combating this view he dealt with the radical changes which have been effected within the past four years. Rubber gloves are now universally worn not alone in abdominal but also in vaginal operations. The rinsing the cleansed hand in methylated spirit, and the partially filling the gloves with similar fluid, enables them to be readily slipped on, and secures an almost aseptic condition of their contained fluid contents, even after they have been worn during a two-hours' operation; thus injury to the glove is not fraught with fear of septic infection through oozing of its fluid contents. We now dispense with much of the elaborate ritual formerly considered necessary in hand-washing. Skin maceration in the neighbourhood of the field of operation is prevented by painting the surface over with a saturated solution of picric acid in spirit. This solution is also of great use when applied to papillary erosions of the less chronic type.

VAGINAL SURGERY.

In vaginal surgery the field of operation has been rendered more sterile by the clipping of a strip of boiled Billroth tissue across the perinæum to shut off the anal region, whilst the bags which enclose the legs are now connected with an abdominal apron which prevents the operator's hands being contaminated in the event of his having to pause in the midst of an operation to make a bi-manual examination. The large semilunar incision of Strasseman provides a rapid and ready method of separating the bladder from the cervix, and performing extensive operations through this route. For vaginal fixation the older T-shaped incision is to be preferred, but here again an improved technique is adopted in that the peritoneum is now insinuated between the vaginal wall and the fixing sutures of the uterus. The technique for the cure of cystoceles and rectoceles has been much improved—in the former by tucking up the bladder and rolling it inwards on itself with fixing catgut sutures, and in the latter by joining again the fibres of the levator muscle and pelvic fascia. The vaginal operation for cancer of the uterus is much more extensive than formerly. Pus tubes are dealt with in a way that almost ensures a safe recovery. If very acute the abscess can be opened by entering the abdomen through the posterior fornix, and directly draining through this hole. If a relapse takes place the pus is rendered less septic, and the case may be considered alone amenable to the more radical operative procedures. In this eventuality he strongly advised the splitting of the uterus in two halves, the insertion of the whole hand into the abdominal cavity, the breaking down of adhesions, and the forcible dragging out of the diseased tube with its attached half of the uterus, the clamping of the tubes outside the vulva, the pushing the clamps into the abdomen, and the insertion of iodoform gauze between them (Landau's operation). Atmocausis has enabled many hæmorrhagic cases to be cured that formerly would have required removal of the uterus. Through the abdominal route pus tubes can be removed with greater safety than formerly by the plan of splitting the uterus down the centre and removing them together with that organ. Tubes affected with interstitial salpingitis are re-sected, and their lumens made patent. Ovaries are freely resected rather than sacrificed. Raw surfaces are covered over with peritoneum. It is now a matter of indifference (so far as the primary operation is concerned) as to whether the uterus is removed with or without its cervix. Both operations have become easy and safe in their performance, whilst unpleasant after-symptoms have been obviated by the non-removal of the ovaries. In spite of this advantage the operation is less often done than formerly, because of the advantages offered by myomectomy as now performed. The uterus can be split in halves, the myomas enucleated from its walls, and the organ again stitched up after the manner which obtains in Cæsarean section. Operative treatment for cancer of the uterus has been revolutionised. Formerly, if the organ was fixed, it could not be readily pulled down, or had its cervix badly eroded, surgical relief was unobtainable. It is pleasant to contemplate that gynæcologists are no longer deterred from relieving the suffering woman, even though prolonged immunity from the disease cannot be promised. The three-layer method of suturing the abdomen has made it possible to operate without any fear of a subsequent hernial formation, and the sub-cuticular skin suture threaded through a leaden plate placed on the wound throughout its entire length has made scar deformity a negligible factor. Anti-streptococcus serum (Polyvalent variety), if administered in suspected cases before symptoms have developed, provides a prophylactic agent against many forms of sepsis. Fowler's position, too, is employed from the first in these cases, and Mr. Moynihan's enthusiastic advocacy of continuous rectal irrigation on the appearance of the earliest symptoms of abdominal sepsis has in all likelihood placed in our hands another valuable therapeutic agent. The President concluded by expressing the hope that he had shown that gynæcology had not stood still, but that its advance had been as great in recent years as throughout any period of its existence.

Dr. A. N. **Holmes** exhibited cases of (*a*) carcinoma of ovary, and (*b*) cystoma of ovary, both from patients, æt. 48, and in both of whom great difficulty was experienced in getting into the abdomen. Both patients had also made a good recovery. In the first case the woman's last pregnancy had been a year previously, and after it the menses had ceased. In the second case the woman had never been pregnant. The chief points of interest were that in the second case extensive adhesions had been set up without causing symptoms, while in the first case the symptoms had been coming on for three years, and it was curious that the disease had not spread further than it did.

Sir A. V. **Macan** said the cases presented more than the ordinary difficulties, and expressed his admiration of the successful results obtained.

Dr. **Purefoy** said he had been indebted to Dr. Holmes for giving him the opportunity of assisting at the cases. The nature and extent of the adhesions in the first case had impressed him fully that the disease was malignant, and he was greatly surprised when Dr. Rowlette told him it was not. It was surprising also that in the second case there should have been such continuous improvement in the woman's condition. His experience of malignant ovarian tumour had been that recurrence, ending fatally, took place within a few months.

Dr. **Rowlette** said that, as far as could be made out from the clinical history of the case of carcinoma, it was a case of primary carcinoma of the ovary, which was said to be a rare disease. That, however, was not the experience of the Dublin Gynæcological School. The pathology of the tumour was what was usual. It consisted of large cells without any special arrangement in glandular formation. Looking at the first case with the naked eye, one would take it to be malignant, but there was some twisting of the pedicle, which led to great congestion and had been the cause of the inflammation which resulted in the adhesions. He could not offer any suggestion as to the cause of the adhesions in the other case.

Dr. **Henry Jellett** said he had seen several cases in which there was no evidence clinically of any primary infection elsewhere, and he had lately seen three cases in which there was a positive primary focus elsewhere. It was very curious that if the ovary was really the seat of the primary disease the cancer should be double.

The **President** said he was afraid that the cancerous tissue had worked itself through the adhesions, and made a permanent cure impossible—though not necessarily so.

The **President** exhibited a uterus removed by Wertheim's operation in which the amount of adjoining tissue taken away was greater than any he had ever seen. Wertheim said the ureter should not be disturbed from its bed. In at least one-third of his (Dr. Tweedy's) cases the cancer had got below the ureter, which had to be lifted in order to dig the cancer out. It was becoming a common thing with him to put a bullet forceps under the ureter and then to lift it up with the forceps while he took away the cellular tissue beneath. He had frequently had the ureter lying out of its bed through its whole extent, and yet he had never had a leakage or a fistula, which showed that there was a great deal too much respect paid to the ureter.

The following card specimens were shown:—

(1) The **President**—(*a*) Adeno-carcinoma of body of uterus, 2 specimens; (*b*) epithelioma of cervix uteri, 2; (*c*) carcinoma of ovary, 2; (*d*) ovarian cyst, 6; (*e*) fibro-myoma of uterus, 7.

(2) Dr. **Purefoy**—(*a*) Dermoid ovarian cyst; (*b*) uterine fibroids removed by myomectomy.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, November 21st, 1907.

The President, Mr. **Frank T. Paul**, F.R.C.S., in the Chair.

NATURAL COLOUR PHOTOGRAPHY IN DISEASES OF THE SKIN.

Dr. **Walter C. Oram** exhibited a selection of photographs in natural colour of various diseases of the skin taken by the new Lumière process, and gave a short account of the theory of the process.

Drs. **G. Stopford Taylor** and **R. W. Mackenna** gave a demonstration of colour photographs of skin diseases taken by the new Lumière process. Dr. Mackenna said that to photograph diseases affecting the skin was to put any process of colour photography to a severe test, and in this the Lumière process had not been found wanting, for it faithfully reproduced the most delicate gradations of colour with an accuracy never attained by the artist's brush. Their main difficulty had been to obtain definition. Since an adequate supply of autochrome plates had been procurable in this country, the weather conditions had been much opposed to successful photography. As a result their exposures had to be prolonged, and they had not found it possible to work with a smaller aperture than F.8. Their shortest exposure had been 48 seconds, and their longest 20 minutes, but they had great hopes that when the light improves again it would be possible to obtain photos not only perfect in colour but rich in detail. The photographs shown illustrated various forms of eczema, psoriasis, scabies, syphilitic eruptions, and tertiary ulcerations before and after treatment, lupus and tuberculosis cutis, acne vulgaris, medicinal eruptions, and sycosis. To photograph a rose ablaze with colour, or a gaudy orchid, is one thing; to get a correct colour picture of a disease whose hue varies but little from the colour of the surrounding skin is quite another matter; but the autochrome plates survive the ordeal triumphantly.

Dr. K. **Crossman** gave an account of photography in natural colours by the three-colour method. The colour screens used for producing the three negatives were demonstrated; also the three positives printed from the three negatives in their respective complementary colours. The three negatives were to be superimposed, and, if well done, this gave the correct representation of the original. The process was laborious and required a great deal of time. A number of slides of test objects, of leprosy patients, and of microphotographs were shown.

NOTIFICATION OF BIRTHS ACT, 1907.

Dr. E. W. **Hope** read a note on the objects of the above Act of Parliament. A declining birth-rate and a high infant mortality had led to various legislative measures designed to lessen the loss of infant life. The Act in question would enable help and guidance to be given to poor women at an earlier period of the infant's existence than was possible now, and it was hoped that such assistance may lessen the mortality during the earlier weeks and months of life which occurred to so great an extent in Liverpool and elsewhere. The obligations upon the medical man were not arduous, but it was hoped that in every case in which a medical man was in attendance the fact would be stated upon the form for notification, and in these cases no visit would be paid by the officer of the Health Committee unless it was specially asked for. Out of the 24,000 births which took place annually in Liverpool, it was estimated that 15,000 were attended by midwives, nearly all of whom were well trained and fully qualified.

Dr. **Albert Davis**, C.C., was opposed to the adoption of the Bill on the ground that notification involved a breach of professional confidence.

Sir **James Barr** moved the following resolution:—"In the opinion of this meeting of the members of the Liverpool Medical Institution, the Notification of Births Act, 1907, should be adopted by the County Borough of Liverpool."

Dr. **William Carter** seconded the resolution, and said that everyone should support to the utmost Dr. Hope in his effort to check the waste of infant life in Liverpool. The startling fact that, of the total number of deaths (4,137) under one year of age last year, 1,057, or more than a quarter, took place in the first month of life, showed the importance of early information being given, so that skilled members of the female sanitary staff might visit the mothers, who were often very ignorant of the duties of motherhood, and, when necessary, give them kindly instruction in the way to rear their infants. "Why," he asked, "should it be a breach of confidence on the part of the doctor to state within 36 hours after birth a fact which must of necessity be known six weeks after it?"

Dr. A. **Stookes** and Dr. J. R. **Logan** having spoken in its favour, the resolution was carried with two dissentients.

A CASE OF PARAPLEGIA TREATED BY OPERATION.

Dr. W. B. **Warrington** and Mr. K. W. **Monsarrat** showed a patient who suffered from paraplegia due to an intra-medullary lesion, and who had been treated with some success by the removal of a local accumulation of fluid. The patient, a young man, was able to walk across the floor of the lecture theatre with the aid of crutches.

Mr. R. W. **Murray**, Dr. F. J. S. **Heaney**, and Dr. **Stansfield** discussed the case.

Mr. **Rushton Parker** showed two patients in whom he had obtained union of previously un-united fractures of the humerus by means of implantation of bone.

CENTRAL MIDWIVES' BOARD.

A meeting of this Board was held on Thursday last, at which matter of importance to medical men was discussed. We regret that, owing to great pressure on our space, our report, which is in type, had to be held over until our next.

GENERAL MEDICAL COUNCIL.

EIGHTY-SIXTH SESSION.

First Day, Tuesday, November 26th, 1907.

Dr. MacAlister, President, in the Chair.

The **President** delivered the following address:—

Gentlemen,—Although in no fewer than eight cases the tenure of office of members of the Council has expired during the recess, in every instance the outgoing member has been re-elected; and I have thus the satisfaction of reporting that the composition of the Council is unchanged. [The eight re-elected members are:—Dr. P. H. Pye-Smith, University of London (one year); Mr. A. H. Young, Victoria University of Manchester (one year); Dr. A. G. Barrs, University of Sheffield (three years); Sir J. W. Moore, R.C.P., Ireland (one year); Dr. F. G. Adye-Curran, A.H., Dublin (one year); Sir C. L. Nixon, Royal University of Ireland (five years); Dr. D. C. McVail, Crown Representative, Scotland (five years); Dr. J. Little, Crown Representative, Ireland (five years).] I may be pardoned for noting that, for the first time in our history, we are able to count a Lord Mayor among our colleagues, Dr. Caton, who has, by the suffrages of his fellow-citizens, been raised to the chief magistracy of the city of Liverpool.

The petition and draft supplementary charter for the erection of a medical faculty in the University of Wales were submitted to you last year, and it was agreed that no objection should be taken to the grant proposed. A provisional committee of advice, to be called the Medical Board, is to be instituted, whose duty it will be to make to the University Court recommendations and reports on all matters concerning the faculty of medicine. The statutes provide that one member of this Board shall be appointed by the President of the General Medical Council.

It is clearly intended that the new degrees shall represent a high standard of general and professional attainment. It is, of course, understood that, without further legislation, these degrees will not admit their holders to the privileges of registration; nor will the University which confers them be entitled to representation on this Council. But it cannot be doubted that proposals for such legislation will ere long be made, and that you will in due course be required to express an opinion upon them.

The prospect of a further increase in our membership makes it necessary to have regard to the financial position of the Council. By the exercise of economy of time and money we have succeeded in reducing our expenditure; but our income, derived for the most part from registration fees, is not increasing, and is not likely to increase. While it is to be hoped that the efforts of the Council to improve the educational attainments of our future practitioners have not been without effect on the efficiency of those we admit to the Register, we must not ignore their inevitable tendency to reduce the number of persons duly qualified for the public service, and incidentally to diminish the available resources of the Council itself.

We may expect fresh light on these direct and indirect effects of our own action, from the laborious analysis of statistics respecting the ages and courses of study of students recently qualified, which has been undertaken by the Education Committee under the direction of its Chairman, Dr. Mackay. In pursuance of your resolution of May 30th, much valuable information on these points has been furnished by the licensing bodies during the summer. . . . One necessary advance, however, has lately been made by the Council. I refer to the new requirements in respect of training in practical midwifery. That such an advance was opportune, if it was not overdue, appears to be generally conceded by the profession. That the advance involves practical difficulties, which in certain medical centres are not easy to overcome, is also clear. . . .

Since we last met, the Bills for the protection of the public by checking the abuses incidental to the practice of medicine and of dentistry by limited companies, which were introduced by Lord Hylton in the Upper

House, have been further considered by Parliament. As you will remember, the Bills were framed under skilled advice, and received your approval as embodying real improvements on the existing law. The Medical Bill prohibited under penalties the practice of medicine or surgery by companies. The Dental Bill sought to provide that every person who under the name of a company treated or professed to treat patients, should himself be a legally qualified dentist.

The Bills, having passed the second reading without objection, were referred to a Select Committee of the House of Lords. The Medical Bill seemed to find favour with the Committee, and being reported without amendment to the House, was duly passed and sent down to the Commons. The exigencies of business, however, prevented its further progress in that House, and with many other measures it was dropped at the end of the session. The Dental Bill was strongly opposed in Committee. Witnesses representing companies of unregistered persons objected that it was unjust to restrict practices which the present Law of Companies had allowed to grow up. Others on behalf of the British Dental Association urged that the Bill did not go far enough in the direction of restriction. It allowed dental companies to exist as commercial entities, though they could only act by means of dental operators who were duly qualified. The evidence has been published, and is worthy of careful study. It illustrates at once the abuses which the Bill sought to remedy, the objections entertained by the officers of the Dental Association to anything short of the total suppression of companies in connection with dentistry, and the strength of the opposition to suppression which such companies are able to offer. In the end their lordships appeared to be influenced by the arguments of the companies rather than by those of the Association. Amendments were introduced with the object of saving for a period of years the interests which existing companies alleged; but nothing was done to make the Bill more drastic in its ultimate operation, as the officers of the Dental Association desired. Fortunately the amendments, as drafted, proved to be unworkable; and inasmuch as, apart from this defect, they seriously diminished the protection to the public which the Bill was intended to afford, it was intimated to Lord Hylton that the approval of the Council could not be held to extend to the measure in its amended form. His lordship thereupon obtained leave to withdraw the Bill, and it was not further proceeded with.

Being assured that it would be your wish, I conveyed to Lord Hylton an expression of the Council's grateful appreciation of his efforts to procure, in the public interest, a useful amendment of the law, and of his able conduct of the proceedings before the Select Committee.

The Companies Bills Committee will meet during the session to consider what steps should next be taken to give effect to the Council's instructions on the questions referred to them. . . . In the meantime certain cases have been decided in the Courts which may have an important bearing on the subject. . . . The Irish Branch of the British Dental Association has been both active and successful in the prosecution of test cases wherein these important issues have been raised, and have been settled so far as Ireland is concerned. . . . It is much to be desired that similar cases should be brought before the Courts on this side of St. George's Channel. . . .

Last May I referred in my address to certain decisions given in the Chancery Division of the High Court which touched upon the scope of your judgment of "infamous or disgraceful conduct in a professional respect," delivered in connection with an inquiry into the methods adopted by certain members of a notorious dental company. The decisions in question were subsequently reversed in the Court of Appeal, and when the cases were brought last week before the House of Lords, the reversal was sustained. The Lord Chancellor, in giving judgment, put aside as immaterial the question whether, in the circumstances of the particular action, the order made by the Council should have been admitted in evidence or excluded. But he pronounced in forcible terms, and the other Law Lords agreed with him, that the facts proved, which were those on which the Council based its judgment, did constitute "disgraceful conduct" and "professional misconduct." Thus, although the decision of the Council was not in form reviewed by the highest tribunal, the grounds of its decision were indirectly declared to be amply sufficient to justify its sentence.

The November session of the Council is in practice specially appropriated for penal business, and I regret to say that on this occasion the greater part of our time will necessarily be occupied by inquiries into cases of alleged misconduct. . . .

From information which has reached us from Canada, it appears that the provincial authorities in Quebec have agreed to a modification of the local law which assimiliates it to the provisions of Part II. of the Medical Act, 1886, and removes the difficulties in the way of medical reciprocity to which I referred in my last address. The formal notification of the change has not yet reached the Privy Council, and so we shall not be required to take any official action at this session.

In the Province of Nova Scotia, which has already begun to furnish us with applicants for home registration, legislative changes have been made which fulfil the expectations of the Executive Committee respecting the assimilation of the provincial curriculum to that which is in force at home. In other words, the recognition of Colonial diplomas by the mother country has had once more the gratifying effect of improving the conditions of medical education beyond the borders of the United Kingdom.

Moved by Dr. LITTLE, seconded by Dr. NORMAN MOORE, and carried by acclamation:—"That the President be thanked for his address, and requested to let it be printed in the minutes."

Moved by Dr. NORMAN MOORE, seconded by Mr. THOMSON, and agreed to:—"That the Council do adjourn at 4 p.m. to-day, to enable certain Committees to meet for the completion of their reports."

Moved by Dr. MCVAIL, seconded by Sir JOHN WILLIAM MOORE, and agreed to:—"That the yearly tables for 1907 be received and entered in the minutes":—(*a*) Table showing results of competition held on November 11th, 1907, for commissions in the medical staff of the Royal Navy. (*b*) Table showing results of competition held on July 25th, 1907, for commissions in the Army Medical Service. (*c*) Table showing results of competition held in July, 1907, for commissions in the Indian Medical Service.

Moved by Dr. MCVAIL, seconded by Sir JOHN WILLIAM MOORE, and agreed to:—"That the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy, the Director-General of the Army Medical Service, and the Under-Secretary of State for India respectively, for the returns which they have again furnished to the Council, with the request that these returns may in the future continue to be furnished to the General Medical Council."

Moved by Dr. PYE-SMITH, seconded by Dr. MCVAIL, and agreed to:—"That the following recommendation of the Executive Committee be adopted, viz., 'That the Standing Orders, Cap. XI., 8, be amended so as to read as follows':—'The fees for attendance at meetings of the Executive Committee and the Penal Cases Committee shall be five guineas a day, and at meetings of the Branch Council two guineas a day for each member attending, his travelling and hotel expenses being also paid.'"

Moved by Dr. NORMAN MOORE, seconded by Mr. MORRIS, and agreed to:—"That the report from the Executive Committee dealing with an appeal to the Privy Council against the decision of the General Medical Council of Mr. James Wilkinson for registration under the Medical Act of Queensland which had been dismissed by the Privy Council be received and entered on the minutes."

Moved by Dr. LANGLEY BROWNE, seconded by Dr. MACMANUS:—"That this Council, deeming it to be contrary to the public interest that any person other than duly qualified practitioners in medicine and surgery should practise medicine in Great Britain and Ireland, appoint a Committee to draft such amendments of the Medical Act as may be necessary to secure this prohibition, and to report to the Council at the session in May."

Dr. Langley Browne, with the consent of his seconder and of the Council, withdrew his motion, and substituted the following:—"That a Committee be appointed to ascertain what legal provisions exist in the Colonies and Dependencies of the Empire and in foreign countries for the prevention of medical practice by other than legally qualified persons, and to consider what steps should be taken to procure effective legislation for the same purpose in the United Kingdom of Great Britain and Ireland."

Strangers by direction of the Council then withdrew in order that the Council might consider *in camerâ* certain items in the Programme of Business.

Strangers having been readmitted the President announced that the Registrar had been directed to restore the name of John Bate Bawden to the *Medical Register.*

The President further announced that the following had been appointed members of the Committee on the Prevention of Medical Practice by Unqualified Persons:—Dr. MacManus, Dr. Norman Walker, Dr. Saundby, Mr. Morris, Dr. Langley Browne, Dr. Latimer, Dr Kidd, Sir John Moore.

Moved by Dr. **Pye-Smith**, seconded by Mr. **Tomes**, and agreed to unanimously:—"That, on the recommendation of the Executive Committee, Mr. Norman C. King be appointed Assistant Secretary to the Council, at a stipend of £260 a year; and that the stipend of Mr. Storrs and of Mr. Cockington be increased to £225 a year."

Moved by Dr. **Norman Moore**, seconded by Dr. **Little**, and carried with acclamation:—"That the Council receives with regret the resignation by Dr. Pye-Smith of his office as Senior Treasurer, and expresses to him its thanks for his valuable services during the last six years."

The Council then adjourned.

Second Day, Wednesday, November 27th, 1907.

The minutes of the last meeting having been read and confirmed, the Council proceeded to the consideration of the case of John Sandilands, registered as M.B., Mast. Surg. 1888, M.D. 1894, Univ. Glasg., of the United Free Church of Scotland Mission, Bhandara, Central Provinces, India, who had been summoned to appear before the Council to answer the following charges, as formulated by the Council's solicitor:—

"That you unlawfully caused miscarriage to an orphan girl under your charge, of which offence you were on the 25th day of March, 1905, and subsequently on appeal on the 10th day of July, 1905, convicted at Bhandara, Central Provinces, India, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

Dr. Sandilands was called, but did not answer to his notice.

The Solicitor read the notice to attend, the receipt of which had been acknowledged by Dr. Sandilands.

The Solicitor also read the finding and sentence in the Magistrate's Court at Bhandara, and the judgment of the Judicial Commissioner on appeal.

Dr. Sandilands being absent this closed the case.

The Council then deliberated on the case *in camerâ*.

Strangers having been re-admitted, the President announced the decision of the Council as follows:—

That the Council have judged John Sandilands to have been guilty of infamous conduct in a professional respect and have directed the Registrar to erase from the *Medical Register* the name of John Sandilands.

The Council considered the case of Edward John Havens, registered as of East Donyland, Colchester, Mem. R. Coll. Surg. Eng. 1879, Lic. Soc. Apoth. Lond. 1879, who had been summoned to appear before the Council on the following charges:—

"That you were on November 5th, 1906, convicted of the following misdemeanour at Thorp Petty Sessions, Thorp-le-Stoken, Essex, namely, of obstructing the highway; also that you were on December 17th, 1906, convicted at the like Session of disorderly behaviour whilst drunk; and also that you were on April 8th, 1907, convicted of the following misdemeanour at Mistley Petty Session, namely, of common assault."

At the conclusion of the proceedings on May 29th, 1907, the President, addressing Mr. Havens, said:—

"Mr. Edward John Havens,—The Council have deliberated carefully on the convictions which have been proved against you, but they have adjourned the further consideration of your case till the November Session, when you should be present to hear the result of their final deliberations."

Mr. Havens attended in answer to his notice.

The Solicitor put in the notice to attend, which had been acknowledged by Mr. Havens, and read a letter from Messrs. Birkett, Ridley, and Francis, his solicitors, dated November 4th, 1907, and a letter from Mr. Havens himself, dated November 7th, 1907.

The Solicitor also reported as to the result of his inquiry concerning Mr. Havens' conduct in the interval since the last session, and read letters which he had received from the Clerk to the Magistrates.

Mr. Havens denied the accuracy of the account given by the police in regard to his conduct, and addressed the Council in his own behalf. He did not tender any evidence in support of his statements, or as to his conduct during the interval.

The Council deliberated on the case *in camerâ*.

Mr. Havens and strangers having been re-admitted, the President announced the decision of the Council as follows:—

Mr. Edward John Havens, the Council having further considered the convictions proved against you, does not direct the Registrar to erase your name from the *Medical Register.*

The Council considered the case of William Shaw, registered as of Larne, Co. Antrim, Lic. R. Coll. Phys. Edin., 1886, Lic. R. Coll. Surg. Edin., 1886, who had been summoned to appear before the Council to answer the following charges, as formulated by the Council's solicitor:—

"That you were on November 27th, 1906, convicted of the following misdemeanour at Larne Town Court, namely, of being guilty while drunk of riotous and disorderly behaviour; and on June 25th, 1907, of the following misdemeanour at Larne Petty Sessions, namely, of being found on unlicensed premises on Sunday in contravention of the provisions of the Licensing Acts; and on August 13th, 1907, at Larne Town Court aforesaid, of the following misdemeanour, namely, of being guilty while drunk of riotous and disorderly behaviour."

Mr. Shaw attended in answer to his notice, accompanied by his solicitor, Mr. W. M. Woodhouse, of Messrs. Peacock and Goddard, of Gray's Inn.

The Solicitor having read the notice, and the three certificates of conviction, Mr. Woodhouse addressed the Council on behalf of Mr. Shaw, and read letters in his favour from Mr. James Adrain, M.B. Bac. Surg., of Larne, Mr. J. W. McNinch of the Larne Cottage Hospital, Mr. Thomas Milliken, Justice of the Peace for County Antrim, and the Rev. Mr. D. H. Hanson.

He then tendered Mr. Shaw as a witness, and examined him. Mr. Shaw answered questions put to him, through the chair, by members of the Council.

The Council deliberated on the case *in camerâ*.

Mr. Shaw and strangers having been re-admitted, the President announced the decision of the Council as follows:—

Mr. William Shaw, the Council have deliberated on your case, and having carefully considered the convictions recorded against you, have not seen fit to direct the Registrar to erase your name from the *Medical Register.*

The Council considered the case of Duncan Shaw Morrison, registered as of Invergowrie, Perthshire, M.B., Mast. Surg., 1891, Univ. Edin., who had been summoned to appear before the Council to answer the following charges, as formulated by the Council's solicitor:—

"That you were on September 24th, 1906, convicted of the following crime or offence at Lochgilphead Police Court, namely, of breach of the peace, and on February 11th, 1907, at the same Court, of the same crime or offence, and on September 18th, 1907, at the same Court, of the following crime or offence, namely, of a contravention of Section 70 of the Licensing (Scotland) Act, 1903."

Mr. Morrison was called, but did not answer to his summons.

The Solicitor read the notice and the three certificates of conviction; he also read a letter which he had received from Mr. Morrison in answer to the charge.

The Council then deliberated on the case *in camerâ*.

Strangers having been re-admitted, the President announced the decision of the Council as follows:—

I have to announce that the Council have adjourned the consideration of the three convictions proved against Mr. Morrison until the May Session, 1908, when he will be required to be present.

The Council considered the cases of John P. Rafter, registered as of 338, Stanley Road, Bootle, Liverpool; Lic. Apoth. Hall, Dubl., 1882; Lic. K.Q. Coll. Phys. Irel., 1886; Lic. Midwif., 1892, R. Coll. Surg. Irel.; and John Spencer-Daniell, registered as of the Metropolitan Hospital, Kingsland Road, London, N.E.; M.B., Bac. Surg., 1906, Univ. Edin., who have been summoned to appear before the Council on the following charge:—

"That you have systematically sought to attract patients in Great Crosby and Waterloo, Lancashire, by the distribution of cards from house to house and in the street, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the Medical Defence Union.

Mr. Rafter attended in answer to his notice, accompanied by his solicitor, Mr. Smith, of Messrs. James Shakespeare and Smith, of Liverpool. Mr. Spencer-Daniell also attended in answer to his notice, but was not represented by counsel or solicitor.

Dr. Bateman appeared on behalf of the Medical Defence Union, the complainants.

The Solicitor having read the notice, Dr. Bateman opened the case for the complainants.

He read correspondence which had passed between himself as Secretary of the Medical Defence Union, by whom many complaints had been received, and Mr. Rafter and Mr. Spencer-Daniell.

He then read several statutory declarations.

Mr. Smith addressed the Council on behalf of Mr. Rafter. He tendered Mr. Rafter as a witness, and examined him.

Mr. Rafter was then cross-examined by Dr. Bateman. Dr. Bateman read a letter which he had received from the Royal College of Physicians of Ireland, with reference to a complaint of a similar character which had been made against Mr. Rafter eleven years ago, concerning which he had cross-examined Mr. Rafter.

Mr. Smith re-examined Mr. Rafter, who answered questions put to him by the legal assessor, by the chair, and by members of the Council through the chair.

Mr. Smith then called Mr. Frederick Jackson, Mr. Rafter's dispenser, as a witness, and examined him.

Dr. Bateman cross-examined Mr. Jackson. Mr. Smith did not desire to re-examine Mr. Jackson, who answered questions put to him, through the chair, by members of the Council.

Dr. Bateman did not desire to address the Council again in regard to the case as it affected Mr. Spencer-Daniell, who then addressed the Council on his own behalf. He handed in a letter and testimonials which had been written on his behalf.

Dr. Bateman cross-examined Mr Spencer-Daniell, who also answered questions put to him, through the chair, by members of the Council. The letter from Mr. Peter Daniel, of the Metropolitan Hospital, which Mr. Spencer-Daniell had handed in, was read.

Mr. Smith put in testimonials which had been given to Mr. Rafter in 1906.

The Council deliberated on the case *in camerâ*.

Mr. Rafter, Mr. Spencer-Daniell, and strangers having been re-admitted, the President announced the judgment of the Council as follows:—

Mr. John Rafter, I have to announce to you that the Council have found the facts alleged against you in the notice of inquiry have been proved to their satisfaction, and that they have adjourned the further consideration of your case to the May Session of the Council, when you will be expected to be present and to produce evidence as to your conduct in the interval.

Mr. Spencer Daniell, the Council have deliberated on your case, and have passed the following resolution:—

"That the facts alleged against you in the notice of inquiry have not been proved to the satisfaction of the Council. The case against you is therefore at an end."

The Council considered the case of Joseph Fitzgerald, formerly registered as of 59, Red Rock Street, Liverpool, but now as of Beach Buildings, Queenstown, Co. Cork, Lic. R. Coll. Surg. Irel., 1871, Lic. R. Coll. Phys. Irel., 1873, who has been summoned to appear before the Council on the following charge:—

(1) "That you have acted as cover to an unqualified person, namely, Mr. Hamilton Williams Jolly, and knowingly enabled him to attend and treat patients and otherwise to engage in medical practice as if the said Hamilton Williams Jolly were a duly qualified and registered medical practitioner.

(2) "That you knowingly allowed the said Hamilton Williams Jolly to fill up and sign in your name certificates of death and vaccination in November or December, 1905, and in June, 1907, whereas in fact you had not attended or seen the patients in any of the cases, but the said Hamilton Williams Jolly had alone attended and seen them;

"And that in relation thereto you have been guilty of infamous conduct in a professional respect."

Mr. Fitzgerald was called, but did not answer to his notice.

The Solicitor having proved the sending of the notice, which he read, proceeded to lay the facts of the case before the Council.

The Solicitor read the evidence which had been given by Mr. Hamilton Williams Jolly and Mr. Fitzgerald at the inquest on Jessie Gogarty. He gave a history of the case, and also read letters written by Mr. Fitzgerald to the Registrar and to himself in answer to inquiries and to the notice.

The Council deliberated on the case *in camerâ*.

Strangers having been re-admitted, the President announced the judgment of the Council as follows:—

The Council have judged Joseph Fitzgerald to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the *Medical Register* the name of Joseph Fitzgerald.

The Council then adjourned.

THIRD DAY.—THURSDAY, NOVEMBER 28TH, 1907.

The minutes of the last meeting were read, and, as amended, confirmed

The Council proceeded to the consideration of the case of John Papa Nicolas, registered as of 87, Dowanhill Road, Catford, S.E., M.R.C.S. Eng., L.R.C.P. Lond., 1904, who had been summoned to appear before the Council on the following charge:—

"That you have systematically canvassed in Catford for patients, by personal visits to patients of Mr. Thomas William Atkinson and to others, both while you were in the employment of the said Thomas William Atkinson and subsequently, and that in the course of such canvass you disparaged the qualifications and skill of the said Thomas William Atkinson and extolled your own, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants in this case were the London and Counties Medical Protection Society.

Mr. Papa Nicolas attended in answer to his notice, with Mr. H. J. Randolph Hemming, his solicitor, and witnesses. The latter gentleman was accompanied by a lady, who acted as his adviser, and by a female shorthand writer.

Dr. Hugh Woods attended on behalf of the London and Counties Medical Protection Society, the complainants, also with witnesses.

On question from the chair, Dr. Hugh Woods stated that he had no objection to the presence of witnesses during the hearing; but on Mr. Hemming being asked the same question, he took exception to their presence. Witnesses, therefore, by direction from the chair, withdrew.

The Solicitor having read the notice, Dr. Hugh Woods proceeded to open the case for the complainants.

Dr. Woods called Mr. Thomas William Atkinson, M.B., B.S., R. Univ. Irel., of Berrymead, 78, Bromley Road, Catford, as a witness. He read Mr. Atkinson's statutory declaration, and questioned him as to its accuracy, which he confirmed.

Mr. Atkinson was then severely cross-examined by Mr. Hemming, who, however, was unable to materially shake the statement brought forward by Mr. Atkinson. In the course of the cross-examination, the Legal Assessor of the Council intervened, and on behalf of the President, requested Mr. Hemming to confine his questions to the occasions when Mr. Papa Nicolas had, as alleged, used his opportunities to disparage Mr. Atkinson.

The Legal Assessor at a later stage again objected to Mr. Hemming's cross-examination of Mr. Atkinson. in regard to a conversation which had not taken place in his presence.

Mr. Hemming cross-examined Mr. Atkinson in regard to the statutory declarations which had been prepared in support of the charge, and read statutory declarations made by several of the witnesses contradicting those previously made by them in support of the charge, and put in a declaration by Mrs. Lavallin.

Mr. Hemming asked to see the original letter of complaint. The Council's Solicitor explained that the documents to which parties were entitled were those which were sent to the Council in support of the charge or in answer thereto.

Mr. Hemming pressed his application for the production of the document, and asked for an adjournment to enable him to apply to the Court for a *mandamus*.

Dr. Woods having expressed his willingness that his letter of complaint should be produced, the Council allowed the letter to be read by their Solicitor, and Dr. Woods undertook to supply Mr. Hemming with a copy.

The Legal Assessor explained the procedure of the Council in regard to the matter.

Mr. Atkinson was then re-examined by Dr. Woods, with several interruptions by Mr. Hemming.

Mr. Atkinson answered a question put to him, through the chair, by a member of the Council.

The Council then adjourned.

FOURTH DAY.—FRIDAY, NOVEMBER 29TH.

The minutes of the previous meeting having been read and as amended confirmed, the Council proceeded to the consideration adjourned from Thursday, November 28th, of the case of John Papa Nicolas, registered as of 87, Dowanhill Road, Catford, S.E., M.R.C.S.Eng., L.R.C.P.Lond., 1904.

The complainants in this case were the London and Counties Medical Protection Society.

Mr. Hemming, defendant's solicitor, on the case being called, stated that he had applied for writs of prohibition and of *mandamus* against the General Medical Council and against John W. Atkinson.

The Council having deliberated *in camerâ*, it was announced, on strangers, etc., being re-admitted, that the case was adjourned until the next session of the Council.

The Council next considered the case of William Henry Roberts, registered as of 63, Lower Mount Street, Dublin, Lic. R. Coll. Phys. Edin., 1885, Lic. R. Coll. Surg. Edin., 1885, who had been summoned to appear before the Council at 4.30 p.m., on November 28th, on the following charge:—

"That you have knowingly assisted certain persons who are not registered as dentists, namely, Mr. Keogh, of No. 4, Lower Mount Street, Dublin, and Mr. John Blake Dillon, Messrs. William-Steyn and Mr. M. William-Steyn, all of 23, Rathmines Road, Dublin, in performing operations in dental surgery by administering and offering to administer anæsthetics, and have so enabled these persons to treat patients and to engage in dental practice as if they were duly qualified in dentistry and dental surgery, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the Irish branch of the British Dental Association.

Evidence having been gone into, the President, after the Council had deliberated *in camerâ*, announced that it had been decided that the defendant was to come before the Council next May for judgment.

The Council then proceeded to the consideration of the case of John Bernard Gabe, registered as of Pentrepoth House, Morriston, Swansea, Lic. Soc. Apoth. Lond., 1881, Lic. Fac. Phys. Surg. Glasg., 1881, who had been summoned to appear before the Council on the following charge:—

"That you have employed as your assistant in connection with your professional practice a person not duly qualified or registered under the Medical Acts, namely, Mr. Frank Hannah, and have knowingly allowed him to attend and treat patients in respect of matters requiring professional discretion or skill, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. John Jenkins, of Temperance House, Tirdeunaw, near Swansea.

And of the case of Morgan Watkin Williams, registered as of Trewernen, Llantwitfardre, Pontypridd, South Wales, M.B., Bac. Surg., 1900, Univ. Glasg., who had been summoned to appear before the Council on the following charge:—

(1) "That you, being a duly qualified and registered medical practitioner, while acting as assistant to Mr. John Bernard Gabe, also a duly qualified and registered medical practitioner, by your countenance, assistance, and co-operation knowingly enabled an unqualified and unregistered person, namely, Mr. Frank Hannah, who was also acting as assistant to the said J. B. Gabe, to attend and treat patients and engage in medical practice as if the said F. Hannah were duly qualified and registered;

(2) "That you signed a certificate of death, namely, of Alice Mary Jenkins, which stated that you had attended the said Alice Mary Jenkins in her last illness, and that you last saw her alive on May 4th, 1907, whereas in fact you had not so attended her or seen her, but the said Frank Hannah had alone attended and seen her;

"And that in relation thereto you have been guilty of infamous conduct in a professional respect."

Mr. G. F. Evans, K.C., M.P., appeared for both the defendants.

Evidence on both sides having been heard, the President, after the Council had deliberated *in camerâ*, announced (1) that the facts against Mr. J. B. Gabe had not been proved to the satisfaction of the Council, and (2) that the facts alleged against Mr. M. W. Williams had been proved to the satisfaction of the Council, but that he was called upon to come before the Council next May for judgment.

The Council then considered the cases of Arthur James Arch, of Leicester House, Coventry, registered as Mem. R. Coll. Surg. Eng., 1904, Lic. R. Coll. Phys. Lond., 1904; William Walter Fenton, of Avonmore, Warwick Road, Coventry, registered as M.B., Bac. Surg., 1893, M.D., 1894, Univ. Dubl., Lic. Midwif. K.Q. Coll. Phys. Irel., 1884; Thomas Alfred Hird, Norton House, Coventry, registered as M.B. Mast. Surg., 1882, M.D., 1900, Univ. Edin.; and William James Pickup, Swanswell, Coventry, registered as Mem. R. Coll. Surg. Eng., 1876, Lic. Soc. Apoth. Lond., 1877, M.B., 1880, M.D., 1893, Univ. Lond., who had been summoned to appear before the Council on the following charge:—

"That you have joined with other registered medical practitioners in forming and are one of the medical staff of a dispensary, namely, the Coventry New Dispensary Service, which systematically canvasses for patients, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants are Andrew St. Lawrance Burke, Gosford House, Coventry, registered as Lic., Lic.

Midwif., 1895; R. Coll. Phys. Irel.; Lic., Lic. Midwif., 1895; R. Coll. Surg. Irel.; Alfred Pytches Blanchard Ellis, of Earlesdon House, Earlesdon, Coventry, registered as Lic. Soc. Apoth. Lond., 1896; and John Inman Langley, formerly registered as of Parkside Arcadian Gardens, Bowes Park, N., but now of 14, Warwick Road, Coventry; Mem. R. Coll. Surg. Eng., 1898, Lic. R. Coll. Phys. Lond., 1898, who were represented by Mr. McCardie, barrister.

Mr. J. A. Hird unfortunately died on November 28th.

Evidence having been heard, the Council, after deliberating *in camerâ*, found that the case had not been proved.

The motion by the President, as Chairman of the Companies Bills Committee, "That the following be appointed additional members of the Companies Bills Committee, Sir Charles Ball, Dr. Langley Browne, Mr. Morris, and Dr. Kidd," was carried.

The report from the Education Committee, proposed by Dr. Mackay, seconded by Sir John Moore, was agreed to, adopted, and to be entered on the minutes.

The report from the Pharmacopœia Committee, proposed by Dr. Norman Moore, seconded by Dr. Lindsay Steven, was agreed to, adopted, and entered on the minutes.

The following reports from the Examination Committee, proposed by Dr. McVail, seconded by Mr. Young:—

(*a*) On the returns as to examinations for entrance to the Navy, Army, and Indian Medical Services since the last Session of the Council.

(*b*) On the final examinations (July, 1907) of the Apothecaries' Hall, Dublin.

After some remarks from Dr. Adye Curran with reference to inspectors, were received, adopted, and entered on the minutes.

A report from the Students' Registration Committee, proposed by Sir Hugh Beevor, seconded by Dr. Norman Moore, was received, adopted, and entered on the minutes.

Mr. Henry Morris was unanimously appointed Treasurer to the Council, owing to the resignation of Dr. Pye-Smith.

A vote of thanks to the President was proposed by Dr. Norman Moore, seconded by Sir J. Moore, and carried by acclamation.

The Council then rose.

FRANCE.

Paris, Dec. 1st, 1907.

Artificial Abscess.

A few additional remarks are necessary to complete what we have already written on artificial abscess.

Prompt reaction to the chemical agent injected, constitutes one of the most favourable signs and the rapid and abundant formation of pus should excite no anxiety, as it is a proof of the resisting power of the organism.

Towards the third day the pus begins to form and the abscess opens spontaneously between the sixth and fifteenth day. According to Fochier, the abscess should never be opened, but generally, as soon as fluctuation is well evident and above all if the patient has entered on convalescence, the collection is incised and dressed antiseptically. The wound cicatrizes slowly, a month or more being sometimes neccessary.

The effects of the abscess are as follows:—Immediately after the injection the temperature may rise a little, but as soon as reaction sets in it falls, the pulse becomes less frequent, and the quantity of urine increases, and if albumin exists it is reduced in quantity. This improvement may take place within twelve hours after the injection, but the temperature becomes normal only when suppuration is formed.

The therapeutic method of this artificial pyogenesis may be resumed as follows:—(a) Artificial abscess seems to possess indisputable therapeutic effects in a patient suffering from infection of no matter what source; (b) artificial abscess is indicated in all cases of ordinary septicœmia, after other methods of treatment have failed; (c) an injection of 20 drops of sterilized turpentine into the cellular tissue is sufficient to produce it. The intensity of the local reaction that the injection provokes is in direct ratio with the degree of resistance of the patient; (d) the incision of the abscess must coincide with local abundant suppuration and improvement in the alarming general symptoms; (e) from the moment of the injection to complete cicatrization, the artificial abscess must be treated antiseptically.

Artificial abscess, it must be confessed, is at most an empiric treatment, as its mechanism has never been established, either clinically nor by experiment.

Fochier considers it to be an organ of attraction for the microbes and the toxines.

Dieulafoy is a partisan of the hippocratic ideas of metastasis. For Trifon, the abscess neutralizes the toxines, while Pinna and Mercaudino consider it to be a laboratory for the formation of bactericide, antitoxic substances which penetrate by absorption into the lymphatic circulation.

Thiosinamin in Heart Disease.

For the last few years Prof. Rénon has been utilizing the curious properties of thiosinamin to soften cicatricial tissue, for the treatment of certain valvular diseases of the heart, cardiac symphysis and arterio-sclerosis.

For mitral affection no improvement was observed, but he had considerable success in aortic disease. Patients who could not mount stairs nor carry heavy loads were able to make those exercises without any or but very slight oppression. The arterial tension was lowered, and albumin diminished or disappeared. However, the stethoscopic signs were in no way modified, no difference in the intensity of the souffle was ever remarked. Its effects were limited to reducing the dyspnœa and lowering the arterial tension, advantages that can be appreciated. The solution he uses is:—

Thiosinamin, 15 gr.
Distilled water, 7 dr.

Each subcutaneous syringe contains four-fifths of a grain. Five syringes are injected at the one time, beneath the skin of the abdomen, and repeated every day for a month. The injections are not painful, nor do they produce indurations.

GERMANY.

Berlin, Dec. 1st, 1907.

At the Medical Society, Hr. L. Michaelis reported that he had been successful in producing a direct reaction in a case of hereditary syphilis by making use of a serum of very high power. The reaction of 0.01 corresponded to 0.2 of the other that had been discovered; it was therefore 20 times stronger. For proving the reaction syphilitic liver extract was employed. The reaction was checked by excess of liver extract. From this it followed that this contained the antigen, the material within the patient on the other hand, the "antistoff."

Hr. Falkenstein gave a retrospect of

The Treatment of Gout by Hydrochloric Acid,

after observations extending over five years He reminded his hearers of an address on the same subject delivered before the Society four years ago. He then discussed the nature of gout and its treatment by hydrochloric acid. Since that time he had daily given 50 to 60 drops of hydrochloric acid, and had also carried out the same course of treatment in a large number of other cases. The large doses of hydrochloric acid were perfectly harmless, so long as they were sufficiently diluted and taken along with a sufficient quantity of food. The alkalescence of the blood was not diminished by the acid, nor were the teeth or organs in any way injured.

The speaker proceeded on the assumption that uric acid was harmful only when it was associated with alkalies whereby its tendency to deposit became heightened. In gouty patients the primary fault lay in a deficiency of hydrochloric acid in the stomach. It was only then that imperfect digestion of nuclein-albumen arose, with excessive alkalescence. Where, however, there was disease of the mucous membranes of the stomach, the hydrochloric acid was otherwise abnormal and the deficiency of it was of subordinate importance. During the attack of gout itself hydrochloric acid had no effect; it should rather be used permanently during the intervals.

The objection that not infrequently there were cases of deficiency of hydrochloric acid without gout he rejected; there must be a primary antacidity; imperfect digestion of nuclein-albumen could only originate then, along with excessive alkalescence.

He had treated 390 cases by this method, and divided them into three groups according to their severity and the age of the patient, on which the results of treatment depended. It was only in the most severe and most chronic cases that the progress of the gouty changes could not be influenced.

Hr. Kraus considered the most important thing in the treatment of gout to be the food—the long-continued giving of foods containing no uric acid. Along with this, the long-continued use of mild alkalies appeared to have an effect on the frequency and severity of the attacks.

Hr. Brugsch, in opposition to the reader of the paper, considered gout to be not a hereditary disease of the stomach, but a diseased nuclein tissue change. If the hydrochloric acid constituent of the stomach was greater then the quantity of pancreatic secretion increased and the balance remained always the same. Hydrochloric acid did not cure gout; the chief thing was the diet.

Hr. Falkenstein meant to say that vegetarians even did not get free of their gout, whilst under the use of hydrochloric acid, patients improved, notwithstanding they were taking fresh meat in large quantities.

At the meeting of the 13th ult., Hr. Albu showed a female patient, æt. 72, who for seven years had suffered from a copious fluid discharge from the rectum, which had been collected and examined. It was found to consist of watery thin mucous. Just above the anus a rather large warty growth was felt, which the patient could easily force down by straining. The tumour was certainly not malignant, as a portion examined under the microscope showed. Considering the age of the patient, it was deemed advisable not to operate.

He then showed a tumour taken from a woman, æt. 62, that had been removed two years previously. Here also the growth could be made to protrude from the anus. It was clearly malignant. The removal was carried out by the late Prof. v. Bergmann. Recovery was normal, and the patient had had two years' good health.

Prof. Ewald is about to retire from the editorship of the *Berliner Klinischen Wochenschrift*, and will be succeeded by Dr. Hans Kohn, of that city.

AUSTRIA.

Vienna, Dec. 1st, 1907.

Fistula Gastrocolica.

Falta presented a case of gastrocolica to the Gesellshaft which he operated on in 1902, who came to him then with typical stenosis from ulceration of the stomach, which demanded gastro-entero-anastomosis. In spite of this operation, the ulceration of the stomach still persisted, 1904-5 and 1907. A tube was passed into the stomach, and fæces extracted or vomited. Air was next blown into the rectum, passing up the descending colon with a metallic noise and rush into the stomach, whence it was ejected by the mouth. Water coloured with methylene blue was injected through the rectum, which took the same course as the air, and was thrown out by the mouth. The Röntgen rays confirmed the passage of the air out of the colon into the stomach by a direct communication through which the contents of the colon passed readily into the stomach. Before this time no symptom indicated that a direct communication existed between the stomach and colon. He thought there was nothing left but to perform another operation to correct the morbid change.

Holznecht said he had one of these rare cases where the history of anastomosis appeared to be established, but it was found later that the pylorus was perfectly patent, and no other communication existed.

Eiselberg thought that gastro-enterostomy should only be performed on careful deliberation after opening the parts, and before severing any of the internal organs. There are many of the pyloruses that are unsuitable for removal at one time, but after the ulcers have healed can be removed with advantage.

Traumatic Hæmatoma.

Eiselberg exhibited a boy, æt. 16, with a large soft fluctuating swelling on the left side of the head. Around the base of the tumour it was as hard as bone and painless on pressure, the latter being true of the whole swelling.

The history of the case was that twelve days before this exhibition he had been playing with other boys, and was caught up by the hair of the head on the left side in their fun. On the following day he found it swollen a little, but gave it no further heed; on the second day it was larger, and has gradually increased every day till it has reached the present dimensions.

Syphilis and Valvular Disease.

Fein presented a young soldier, æt. 20, with insufficiency of the mitral valve and complete paralysis of the left vocal cord. The Röntgen rays showed an increase of the heart in all directions, as seen from the pulsating shadow, but no aneurysm could be detected. From the history the young man had syphilis six months previously. Energetic anti-syphilitic treatment was immediately commenced, and the patient improved in voice and general health within three weeks, although the vocal cord had been greatly atrophied The great difficulty in breathing had quite disappeared, and the cardiac sensation had returned to its normal condition. After commencing the inunctions, the vascular walls began to repair rapidly, which is unusual in fresh cases. The widening of the aorta soon began to contract, and thus relieve the vocal nerve.

Perl-Cyst.

Tertsch presented a young female, æt. 20, with a cyst in the anterior chamber of the right eye, the result of a stab. It appears that some of the epithelial cells were carried through the cornea into the anterior chamber, where they commenced to proliferate and form a sac like a hair bulb or gland, and finally attach itself to the iris. Having once got a root, a cyst was formed, till a good-sized tumour was formed, but happily began to break down in the centre. These neoplasms resemble the atheroma or cholesteatoma in the destruction of the eye, and should be removed at the earliest opportunity, as the prognosis is always favourable.

Foreign Body in Trachea.

Marschitz showed a boy, æt. 5, who had allowed a fish-bone to get down the trachea and it was caught at the bifurcation of the bronchi. There was no choking, but sudden aphonia appeared, with difficulty in swallowing. With the laryngoscope the bone could be seen lying in the sub-glottic space directly in the median line. The boy was narcotised, and the body caught with Schrotter's forceps and brought up to the glottis, where difficulty arose to get it through. The child, feeling the pain, made a sudden move, causing the operator to press the body tighter, which broke, allowing part of it to fall back into the bronchi, where it could afterwards be seen with the bronchoscope; it was removed with another pair of long forceps. In spite of this successful removal with the bronchoscope, he thinks tracheotomy the safer operation, as there is not such fear of œdema of the glottis.

CONTINENTAL HEALTH RESORTS

1.—A SUDDEN FLIGHT TO THE SUNNY SOUTH.

[From Our Continental Correspondent.]

Nice is undoubtedly the most important town on the French Riviera. It has become a general favourite with all nations, and with the advent and persistency of the November fogs, the annual migration to the sunny south has been hastened. Thanks to the excellent service of the South-Eastern and Chatham Railway, with their new and fast boats viâ Dover and Calais, Folkestone and Boulogne, and special train service of the popular P.L.M., the Riviera can be reached in comparatively few hours under exceptional circumstances of enjoyable comfort.

The climate of Nice and of Cimiez is dry and bracing, such as to strongly stimulate metabolism. Glorious excursions far and near, and delightful walks in the immediate environs, afford the necessary attractions to those in search of health; and for those who are suffering from nerves, throat troubles, or rheumatic tendencies, Nature and Art appear to have joined hands to render the beautiful region of Cimiez (the favourite resort of her Majesty the late Queen Victoria) one of the most desirable places for winter residence along the Riviera. Excellent hotels also abound, each endeavouring to excel the other in all matters of hygiene, cuisine and comfort, thus leaving power to the visitor to decide according to his tastes or his purse. I would specially draw attention to the recently constructed "Winter Palace" and Hermitage, luxuriously furnished with all home-like comforts, and commanding, as they do, a magnificent panorama, surrounded on all sides by well-kept and picturesque gardens, rejoicing in an atmosphere free from dust and noise. Both ends of this charming resort are to be strongly commended, so that it is purely a matter of personal choice where hotels are all good and do their utmost to satisfy the tastes and meet the wishes of their guests. Excellent concerts twice daily delight the musical ears of those who spend the mornings and afternoons inhaling the ozone-laden atmosphere, together with the tonic woodland and perfume of flowers. Cimiez is not a place for chronic invalids, and it is well that physicians should bear this fact in mind when deciding on a winter health resort for patients; but for people who are convalescent and require bracing up it stands unique. Well-known physicians, English and foreign, are to be found in this ideal spot.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

TREATMENT OF INCIPIENT MENTAL DISEASE.—The question of the treatment of early and "border-line" cases of mental disorder in the Edinburgh Infirmary, which caused a good deal of discussion some years ago, and was then dropped for the time being, has again been brought before the public by a letter from Dr. Clouston, and an editorial which appeared in the *Scotsman* of November 29th. Dr. Clouston recapitulates the facts which were brought out three years ago —the general favour with which the proposal to treat such cases in the infirmary was received by the medical profession; the approbation of the Commissioners in Lunacy; and the welcome of the philanthropic public. The managers of the infirmary, impelled largely by financial considerations, however, decided that the time had not yet come to institute such wards. Since that time, says Dr. Clouston, wards for suitable mental cases have been successfully established in America, Canada, and Australia. "To have a patient suffering from a short attack of child-bed delirium formally committed to a mental hospital on two doctors' certificates and a sheriff's order, when a few weeks' treatment in suitable wards in the Royal Infirmary would cure her disease and restore her again to her family, is almost a scandal." While arguing that this is a question for the public, and not merely doctors to settle, Dr. Clouston goes on to say that the overwhelming opinion of medical men who are specially interested in mental diseases was in favour of the scheme four years ago. Sir Arthur Mitchell, Sir John Tuke, Sir John Sibbald, Dr. Fraser, Dr. Macpherson, Dr. Urquhart, Dr. Robertson, Dr. Bruce, and Dr. Easterbrook are quoted as having supported it. Every general practitioner he has spoken to has backed up his opinion that such wards would be of enormous use, and are urgently needed. Glasgow is ahead of us in this respect, having provided for the treatment of incipient and uncertified mental disease in a way that is doing a great service to the most helpless class of mankind. It appears to Dr. Clouston that the time has now come for the managers of the infirmary to take the matter up. In addition to providing early treatment for cases which are now allowed to drift into incurable mental conditions, such wards would have the great advantage of helping to strengthen in the public mind a realisation of the fact that insanity is a bodily disease, and so remove the reproach or stigma which ignorance or prejudice attach to it. It will be a great gain to Dr. Clouston that he has secured the aid of the *Scotsman* in his crusade, and the strongly-written editorial in which reference is made to his letter will strengthen the hands of those who urge that mental wards are required. The editorial speaks of it as "a highly deserving cause," and emphasises "how seriously defective is our equipment for treating insanity in its curable stages" compared with the provisions made on the Continent. The ground taken is that the infirmary was compelled to defer the scheme because it had other work on hand; now the contributors should recognise that they have an enlarged responsibility, and provide funds for Dr. Clouston's ideal. "It would complete on a side hitherto neglected a great charitable institution for the help of suffering. It would extend the sphere of experience and instruction available for a great medical school. It might even effect some saving in the public cost of maintenance of pauper lunatics in the asylums."

TRINITY HOSPITAL FUND APPOINTMENTS.—The Town Council have appointed the following gentlemen Medical Officers to the Trinity Hospital Fund:—Dr. James Murray, Dr. John McLaren, Dr. J. A. H. Duncan, and Dr. Balfour. The Medical Officership was formerly held by the late Dr. Dunsmure, but when it became necessary to elect a successor, the Council resolved to divide the appointment and elect four medical officers resident in different parts of the city.

SCOTTISH ORPHAN HOMES.—The thirty-sixth annual meeting of these homes, founded by the late Mr Quarrier, was held in Glasgow on November 27th. In the homes on October 31st, 1907, there were 1,268 children—687 boys and 599 girls. In the consumption sanatoria were treated 336 patients during the year. and there were 2,030 attendances at the dispensary. The first home for epileptics has been in operation for 15 months, and is now filled with 30 young men Among those who spoke at the meeting were Dr. W. L. Reed and Professor Stockman. "Quarrier's Homes," as they were formerly called, arose through the labours of one man, and are among the best known charities in Scotland. Everyone has always recognised the admirable way in which they were conducted, and as the Scottish Orphan Homes they will remain as an enduring monument to the memory of their founder, Mr. James Quarrier.

BELFAST.

ULSTER MEDICAL SOCIETY.—ANNUAL DINNER.—The annual dinner of this society was held in the Medical Institute, Belfast, on Thursday, 28th ult., and was a most successful function. The chair was occupied by Dr. John McCaw, the President of the Society. The toast list was brief, and the intervals were filled by songs and recitations by members. After the toast of "The King," proposed by the President, had been drunk, Mr. A. B. Mitchell proposed "The Lord Lieutenant and Prosperity to Ireland," and in doing so appealed to those present to help in promoting this prosperity by spending their holidays in their own country, of the remoter parts of which most know so little. The High Sheriff of Belfast, Dr. Peter O'Connell, J.P., replied, and in an eloquent speech prophesied brighter days for Ireland, in which the members of our profession would occupy important places as the apostles of preventive medicine. "Our Guests" was proposed by Dr. Walton Browne, and responded to by President Hamilton, of Queen's College, and Dr. Warnock, of Donegal, President of the Ulster Branch of the British Medical Association The health of the President of the Society was proposed by Dr. J. B. Moore, and, in replying, Dr McCaw gave some particulars of a golf prize which he is offering for competition among the members this winter. Decidedly the most entertaining item of the evening's programme was the reading by Dr. R. J. Johnstone of a poem, which he said he had been privileged to take down in shorthand on the opening of the Tuberculosis Exhibition in Belfast last week, "The Last Dying Speech and Confession of Bacillus Tuberculosis, Esq., late of Belfast, with a Full History of his many Crimes and Murders, and his most Edifying End." The allusions to the work of Sir John Byers, Dr. Thomas Houston, and others named in the poem were received with great applause, and after the reading Dr. Johnstone quickly disposed of many copies at sixpence each for the benefit of the Royal Medical Benevolent Fund of Ireland.

LAST DYING SPEECH AND CONFESSION OF BACILLUS TUBERCULOSIS, ESQ.

'Twas a weariful bacillus, old and faded, worn and gray,
Who, drying on the coverslip spake thin and far away:
"Proud mortal, ere my form you steep in carbol fuchsin stain,
Ere I bathe in acid alcohol again and yet again,
I would fain recount my story to your sympathetic ear;
But wet my lips with saline, for the Bunsen flame's too near.
I was once a gay young microbe, and I floated round the town,
Wrapped up in well-dried mucus, light as the thistle down.
My race was old and mighty; Koch made us known to fame,
For the Tubercle Bacillus is my far-renowned name.
In the heyday of my vigour, when the world and I were young.
My aims were high—I sought and found the apex of the lung.
With a chemotactic longing leucocytes came flocking round,
We dallied fondly till we changed th' expiratory sound,
So Professor Lindsay spotted me, and ordered me to quit—
I find fresh air unhealthy, I thought it best to flit.
More cautious now, I sought to rest embraced by giant cells,
Within a deep cervical gland that near the phrenic dwells.
Unhappy choice! for Surgeon Kirk removed me all complete,
With half a foot of jugular and half a pound of meat.
My bonds with man, so rudely torn, gave all my faiths a shock,
I doubted—'Am I human? p'raps I ought to try the flock;
I may be bovine after all; since man evicts me still
I'll look for compensation under Mr. Birrell's Bill.
So I found a country dairy, just back of Grosvenor Street;
A friendly stripper took me in and lodged me in her teat
Here, amid rustic sights and smells, I ruralised a space,
Then borne upon a stream of milk rejoined the human race.
Snug in mesenteric nook I soon addressed my mind,
By fission's simple easy arts, to propagate my kind.
Over the serous surface quick spread my hardy brood;
Ascitic fluid came in floods—we found it very good.
But Thomas, prince of opsonists, by fell mischance came nigh:
He took the index of our host, and found it very high.
Treatment on scientific lines we heard him then discuss—
Tuberculin, one milligramme, soon decimated us!
Fleeing the slaughter of my tribe, my powers now rather weak,
With hearty zest I made a nest upon a damask cheek.
There, in an apple-jelly speck, I'd hoped to end my life,
But X-Rays pierced me to the quick—I left th' unequal strife.
Since then I've wandered round Belfast, but find the world grown hard,
Man's bowels yearn no more for me, and bovine beasts are barred.
A band, with demonstrating ways and eloquence profound,
'Gainst me the people's passions raise, and loud the tocsin sound.
Chief instigator of the fray, Sir John—'No quarter'—cries,
When knights were bold they fought with things—well, nearer their own size!
A surgeon, too, a vet. as well, physicians add their breath,
And gents from sanatoria, where we are fed to death,
And several more who show my crimes, while all the people stare;
Though many a fee they've got for me—they'll get no more, I swear!
For now those oft-respired airs, in which a microbe blooms,
Are blown to Hades by the breeze denouncing 'Stuffy Rooms.'
They've cleared away the dust, in which I used to lurk and hope;
They hear 'What other nations do'—the Dutch are fond of soap.
I lived with darling children once, in tissues soft as silk;
I simply can't get near them now—they sterilise the milk!
Aye, worse than that—excuse the tear of pity in my eye—
The poor milch cows that harbour us, for that offence must die.
The very things I most detest I strive in vain to flee,
All round it's sunlight, food, fresh air, to kill 'the Scourge'—that's me.
Why, many good, hard-drinking souls are sorely put about—
They're going to dock the beer, because I like men fond of stout.
At peril oft before I scoffed, I've managed to outpace
The dreaded phagocyte's pursuit, his fatal slow embrace;
I've laughed to scorn iodoform, and once—'twas rather warm—
Passed through a disinfector, hid in blankets, without harm!
But at the fate we've met of late imagination swoons—
Frizzling to death by millions in combustible spittoons!
Well, when assailed by these alarms I had begum to quake,
Professor Symmers welcomed me for old acquaintance sake.
Said he—'Can I believe my eyes, and have we met at last,
Sole Tubercle Bacillus left alive in all Belfast?
Nay, come; I'll gladly take thee in, and gladly give thee place
Upon this spacious agar slope, last scion of thy race.
With glucose will I nourish thee, and human serum, too,
And thou shalt grow apace, and I will put thee oft on view—
The parasite that lived and throve—believe it now who can—
In pre-Exhibition ages on pre-Exhibition man.'"
The murmur ceased, the microbe passed; the relics are on view—
A crimson speck, in balsam, on a ground of methyl blue.

CEREBRO-SPINAL FEVER.—At the last meeting of the Public Health Committee, Dr. Gardner Robb reported that for some time past he has been using a new serum, not yet upon the market, for the treatment of cerebro-spinal meningitis cases, and that the results have been very much better than those obtained from any of the other serums he has tried. Details of this serum will be awaited with interest, as Dr. Robb's very extensive experience gives great weight to his words, and those who know his caution will be the first to expect a good deal of a remedy of which he speaks as he does of this.

LETTERS TO THE EDITOR.

SANDOW AS PHYSICIAN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Ours is a great and noble profession. It involves complete self-sacrifice. Our mission is to succour suffering humanity without any kind of sordid consideration. How much we get paid for arduous services calling for expenditure of our best vital forces, or whether we get paid at all, matters not one jot; we must give ourselves up body and estate to our altruistic mission. With feelings like these which inspire all of us, I am certain every one of your readers has, with me, welcomed the establishment in London within the past few weeks of two noble institutions which promise to bring speedy relief to crowds of sufferers to whom the slow, uncertain methods of scientific medicine are of no use. These two great institutions, "The Nauheim," in George Street, and "The Sandow," in St. James's Street, have been sufficiently referred to in your columns, and have been fully described in articles in the *Times* and all the lay Press. "The Nauheim" establishment cures all the maladies which are uncertainly dealt with at Nauheim itself, besides a good string of diseases not dealt with at Nauheim. It does this by the Nauheim bath treatment and other wonderful methods which a purblind medical profession is not cognisant of. "The Sandow" institution cures the same string of maladies—a few more or a few less—by marvellous muscular exercises of which a quite blind medical profession has never perceived the value. "The Nauheim" institution assures us—although no reasonable man can need such assurance—that the profession was represented by eminent doctors at its opening, and that they are flocking with their patients to enter upon a "new era in medicine." It modestly refrains from giving the name of a single doctor—modesty which every member of the profession, although sympathisingly, must regret. "The Sandow" institution claims, no doubt with equal right, the support of leading doctors, and quite properly puts the name of a distinguished supporter in its advertisements. This gentleman, it seems, is Sir Conan Doyle, who, we are told, has given his imprimatur to the work of Mr. Sandow. I am sure we would all like to back up Sir Conan in his philanthropic endeavours in this connection, and we should all be glad to know from him how best to set about it. Can you, Sir, ask Sir Conan Doyle for an explanation through your widely-read pages?

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.

November 29th, 1907.

[We regret our correspondent, a well-known member of the profession, prefers to withhold his name, and we trust that this fact may not prevent Sir Conan Doyle from acceding to his request. Sir Conan Doyle now holds a position of complete detachment from professional life, and it would be most interesting to learn his views with regard to Mr. Sandow's new pathological ideas and therapeutical practices.—ED. M. P. AND C.]

DO MEDICAL MEN ASSIST IN THE SALE OF PROPRIETARY MEDICINES?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The workers of the medical profession, *i.e.*, those who have to gain their living solely from what the practice of their profession produces, will be grateful for your leading article on, "Do Medical Men Assist in the Sale of Proprietary Medicines?" Every sensible man of business knows that they do assist, and that for many practitioners the Pharmacopœia might almost as well be non-existent, as So-and-so's special preparation is almost invariably ordered. I grant that the manufacturing chemist puts up many of the usual preparations in a pleasant and agreeable form—more pleasant that an ordinary prescription following the lines of the Pharmacopœia would probably be—but does that make it right that leaders of the profession should advise these proprietary or registered formulæ, which are frequently ordered to be dispensed in the original packages? If the Pharmacopœia is defective, it ought to be improved. If special tablets or mixtures are required, it ought surely to be possible to write a prescription for them. Why should medical men recommend some special firm's cod-liver oil, or emulsion, or other such preparation except through laziness; or why should they advise some tablet or varalette which is advertised in all the lay papers as obviating the necessity of incurring a medical bill? Recently I (and I presume most other medical men) have received a reprint of a paper by one of the leaders of the profession advocating the use of a proprietary article in septic throat cases. Need I point the moral that the intelligent but parsimonious public will, at any rate in the first instance, go to their chemist and get a bottle of these tablets, and thus in some cases avoid calling in a medical man, but in other cases the doctor, when called in, will find that a diphtheria has been too long neglected for serum treatment to be of avail.

Yours etc.,

James Hamilton, M.D., Q.U.I.

60, Sydney Street, Chelsea, Nov. 30th, 1907.

CLOSE OF THE MAGUIRE FUND.

To the Editor of The Medical Press and Circular.

Sir,—In sending you the final list of subscribers to the Maguire Fund, which is now closed, I wish to repeat my expressions of thanks to you and to the generous subscribers.

The fund realised in all £63 12s. 6d., a sum sufficient for all present requirements.

	£	s.	d.

* Dr. Elliott, with kind forethought, wishes 10s. 6d. to go to the little boy as a Christmas present.

I am, Sir, yours truly,

R. B. Mahon.

Ballinrobe, November 25th, 1907.

MEDICAL NEWS IN BRIEF

Irish Medical Schools Graduates' Association.

A most successful evening was the result of the autumn dinner of the Association, held on Wednesday, November 27th, at the Hotel Cecil, the President, Sir John William Moore, in the chair. The autumn general meeting of this Association was held before the dinner, Sir J. W. Moore in the chair, when, after the ordinary business, a proposal concerning the formation of a northern branch, to include Manchester, Liverpool, Leeds, Sheffield, and other places near to them, was considered, which was approved by the meeting, the details being left to be worked out by the Council.

About 200 members and guests, including ladies, sat down to the dinner. Amongst those present were Sir John and Lady Moore, Sir James and Lady Digges la Touche, Sir Shirley Forster and Lady Murphy, Sir Dyce and Lady Duckworth, Colonel Sir R. Havelock Charles, General W. Carnell, Surgeon-General Sir Thomas Gallwey, Sir Charles Cameron Lamb, Dr. Macnaughton Jones, Dr. Fegan, Dr. James Little, Dr. F. J. and Mrs. Roberts, Dr. McVail, Dr. James Macan, Dr. and Mrs. Giles, Mr. and Mrs. Chas. Ryall, etc. After the usual loyal toasts, Dr. J. Macan presented the Arnott Medal to Sir R. Havelock Charles. This medal was founded in 1900 by Mr. Arnott in memory of J. Arnott for heroism or distinguished service on duty in civil life or in the naval or military services. It was awarded to Sir R. H. Charles for his very important services in epidemic diseases in India. Sir R. H. Charles said a few graceful words in acknowledgment. The toast of "Our Defenders" was proposed in a very humorous speech by Dr. J. Little, and responded to by Dr. Samuel Browne, R.N., and General William Carnell, the latter making a few terse and soldier-like remarks anent the service he represented. After "Our Guests" had been proposed by Dr. Fegan, and responded to by Sir J. Digges La Touche and Sir Shirley Murphy, Dr. Fred. Roberts gave the toast of "Our Guests" in a few quaint and amusing words, prefacing his remarks by expressing his surprise at having to propose this toast, as he himself was a Welshman. The President, in responding, after a few words about the propinquity of Ireland and Wales, called on Dr. Roberts for a song. Dr. Roberts sang "Tom Bowling," and, as an encore, "My Pretty Jane," in his well-known admirable style. The musical arrangements were in the capable hands (in Irish it would be mouths) of Miss Gertrude Woodall and Mr. Anderson Nicol, Miss Edith Pratt presiding at the piano.

Statute of Limitation.

At Runcorn County Court, on the 14th inst., before Judge Shiress Will, Dr. Carruthers, of Halton, sued George Knight, of 58, Park Road, Southport, "gentleman," for £53 11s. 6d., balance of an account for professional services.

Mr. A. Browne said Mr. Knight was formerly a well-known accountant in Runcorn, but retired some years ago. In 1890 Mr. Knight had a serious illness, and Dr. Carruthers attended him night and day, and had to call in a specialist. Mr. Knight had made two payments of £10, the last in 1897.

Mr. Knight now pleaded the Statute of Limitations, and his Honour said he had no alternative but to give judgment for the defendant. Mr. Browne asked that defendant should not receive costs, but his Honour said the plaintiff could have withdrawn the case when the Statute was pleaded, and he granted defendant costs.

Death under Chloroform.

Mr. Brighouse held an inquiry at St. Helens, on November 23rd, into the death of Richard Mayor, 52, a collier. Mayor died at the St. Helens Hospital on the previous Thursday, while being operated on by Drs. Cotton and Latham. Deceased had been treated for several years, off and on, by Dr. Valentine, of Earlestown, for hernia, and he on Thursday last decided that an operation was immediately necessary. Dr. Cotton said that the operation was started in the usual way, after the condition of the man's heart, etc., had been considered, but very soon after chloroform was administered Mayor collapsed. The operation had not actually been entered upon, and the man died. The Coroner said the percentage of deaths of people under chloroform was very small. Dr. Cotton said that was so. A verdict of "Death from Misadventure" was returned.

The Women's National Health Association.

A meeting was held during the past week at the Royal College of Physicians of Ireland, under the Presidency of the Countess of Aberdeen, for the purpose of inaugurating a Dublin branch of this Association. The meeting was very largely attended, and amongst the audience were a number of prominent members of the medical profession. Her Excellency, in an opening speech, said that the objects of the

Association were threefold. The first was a crusade against tuberculosis. The second the lowering of infant mortality, which was very high in Dublin and Belfast. The third was the improvement of school hygiene. Resolutions were passed inaugurating the branch, and appointing an Executive Committee.

In connection with this meeting it is interesting to note that at a conference of representatives of the Clinical Hospitals of Dublin, held last week, under the presidency of her Excellency the Countess of Aberdeen, it was unanimously agreed to recommend the various Hospital Boards to co-operate with the Women's National Health Association of Ireland in their efforts to provide adequate home treatment for tuberculosis patients.

Royal Medical Benevolent Fund Society of Ireland.

A QUARTERLY meeting of the Central Committee was held at the Royal College of Surgeons on Wednesday, November 27th. Present, Sir Francis Cruise (in the chair). A letter was read from Dr. Minchin, tendering his resignation of the post of hon. secretary and treasurer of the Co. Meath branch. His resignation was accepted, and the secretary was instructed to give the thanks of the Central Committee to Dr. Minchin for his services on behalf of the Society. Urgent applications for grants were then considred, and awards amounting to £54 10s. were made. The meeting then adjourned.

The Normyl Treamtent of Inebriates.

WE understand that the Normyl Treatment Association is about to open a home, near Sevenoaks, for patients suffering from alcoholism who require special care and supervision. The cost, it is understood, will be kept as low as possible, the members of the Association being pledged to make no personal profits. All inquiries should be addressed to the Hon. Secretary, Normyl Treatment Association, 91, Victoria Street, London, S.W.

Plague in India.

A DISTINCT decrease in the plague mortality is reported from Simla. There were in India during the week ending October 26th only 8,785 deaths, of which 7,034 were in the Bombay Presidency, 203 in the Punjab, 236 in the Central Provinces (including Berar), 589 in Mysore State and 229 in Hyderabad State. The remaining provinces returned even smaller totals. Mr. S. H. Butler, C.I.E., Deputy Commissioner, and chairman of the Lucknow Municipal Board, lately presided over a special meeting of the Municipality to consider measures for rat destruction. A number of the general public were present. It was resolved that an active campaign against rats be declared immediately; that a special staff be employed temporarily for this purpose; that poison be laid down systematically in houses where owners consent, and that house to house action be taken with poison, as well as with traps. "Azoa" poison is to be tried experimentally, and a stock of traps will be kept and distributed, as also leaflets explaining the facilities for rat destruction. Representative ward committees were formed and the co-operation of the public gives every hope that the risk of a serious outbreak of plague this season will be greatly minimised.

Sleeping Sickness—Formation of a Committee.

AN independent Sleeping Sickness Committee has been formed in Liverpool to collect information dealing with Sleeping Sickness, and to stimulate research into the cause, method of transference, and cure of Sleeping Sickness, and to publish from time to time communications with reference to this disease. The following gentlemen are members of the Committee:—Sir Alfred Jones, K.C.M.G. (Chairman); The Rt. Hon. the Lord Mayor of Liverpool (Dr. Richard Caton); Professor B. Moore, Director of the Bio-Chemical Department, Liverpool University; Professor Salvin-Moore, Director of the Cytological Department, Liverpool University; Professor Annett, Director of Comparative Pathology Department, Liverpool University; Professor Sherrington, Director of the Physiological Department, Liverpool University; Dr. Stephens, Walter Myers Lecturer in Tropical Medicine, Liverpool University; Dr. Anton Breinl, Director Runcorn Research Laboratories; Dr. Prout, C.M.G.; Dr. Arthur Evans; Dr. M. Nierenstein; J. W. Garrett, International Fellow, Liverpool University; Dr. J. L. Todd, of Montreal.

Corresponding Secretaries:—Professor Sir Rubert Boyce, F.R.S. (Dean of the Liverpool School of Tropical Medicine), and A. H. Milne, B.A., Cantab.

St. Thomas's Hospital, London.

MR. C. A. R. NITCH, M.S.Lond., F.R.C.S.Eng., has been appointed Surgeon to Out-patients at this Hospital.

THE following gentlemen have been selected as House Officers from Tuesday, December 3rd, 1907:—Casualty Officers:—(Senior) C. M. Page, M.B., B.S.Lond., M.R.C.S.; (Junior) C. E. Whitehead, B.A.Cantab., M.R.C.S. Resident House Physicians:—G. G. Butler, B.A.Cantab., M.R.C.S.; S. L. Walker, B.A., B.C.Cantab., M.R.C.S.; W. H. R. Sutton, B.A., M.B., B.C.Cantab., M.R.C.S.; S. Churchill, M.A., M.B., B.C.Cantab., M.R.C.S.; A. L. Loughborough, M.R.C.S., L.R.C.P. House Physicians to Out-Patients:—B. T. Parsons-Smith, M.B., B.S.Lond., M.R.C.S.; A. J. S. Pinchin, M.B., B.S.Lond., M.R.C.S.; H. B. Weir, B.A.Cantab., M.R.C.S.; R. G. Bingham, M.R.C.S., L.R.C.P. Resident House Surgeons:—H. J. Nightingale, M.B., B.S.Lond., M.R.C.S.; H. R. Unwin, M.A., M.B., B.C.Cantab, M.R.C.S.; G. M. Huggins, M.R.C.S., L.R.C.P.; F. M. Neild, M.B., B.S.Lond., M.R.C.S. House Surgeons to Out-Patients:—H. H. Carleton, B.A., M.B., B.Ch.Oxon.; R. E. Todd, M.B., B.S.Lond., M.R.C.S.; W. R. Bristow, M.B., B.S.Lond., M.R.C.S.; H. E. T. Dawes, B.A.Cantab., M.R.C.S. Obstetric House Physicians:—(Senior) H. B. Whitehouse, M.B., B.S.Lond., M.R.C.S.; (Junior) T. G. Starkey-Smith, M.R.C.S., L.R.C.P. Ophthalmic House Surgeons:—(Senior) A. S. Burgess, M.A. Cantab., M.R.C.S., L.R.C.P.; (Junior) A. I. Cooke, B.A., B.C.Cantab. Throat Department:—A. W. C. Drake, B.A.Cantab., M.R.C.S.; H. N. Little, B.A. Cantab., M.R.C.S. Skin Department:—J. F. Windsor, B.A.Cantab, M.R.C.S.; A. L. Sachs, M.A. Cantab, M.R.C.S. Ear Department:—W. Patey, M.B., B.S.Lond., M.R.C.S.; W. G. H. M. Verdon, B.A.Cantab., M.R.C.S. Children's Surgical:—E. C. Sparrow, M.R.C.S., L.R.C.P. Electrical Department, X-Ray Department:—A. L. Sachs, M.A.Cantab., M.R.C.S.

Royal College of Surgeons in Ireland.

Fellowship Examination.—The following candidates having passed the necessary examination, have been admitted Fellows of the College:—R. Counihan, B.Ch., etc., Univ. Dub.; R. W. Haslett, B.Ch., etc., Roy. Univ. Irel.; D. L. Harding, L.R.C.S.I., etc., Captain R.A.M.C.; M. G. McElligot, L.R.C.S.I., etc., and G. A. Walpole, L.R.C.S.I., etc. The following candidates have passed the primary part of the Fellowship Examination:—H. W. A. Kay, student R.C.P. and S.I.; and T. S. Reddy, L.R.C.S., Edin., etc.

Trinity College, Dublin.

The following candidates passed the Final Medical Examination, Part II., during Michaelmas term, 1907:—Midwifery: Gordon A. Jackson, Johannes C. Pretorius, George B. M'Hutchison, Henry H. Ormsby, George Halpin, Wilfred J. Dunn, William E. Hopkins, Samuel F. A. Charles, Gerald G. Mecredy, Herbert V. Stanley, Dixie P. Clement, Thomas Ryan, Ernest C. Lambkin, William H. Sutcliffe, James R. Yourell, James E. M'Causland.

WHILE a drinking fountain erected at Kettering to the memory of the late Dr. Dryland, for many years medical officer of the town, was being unveiled last Saturday by Admiral Lord Charles Scott, that gentleman gave the rope a too vigorous pull, and the upper part of the fountain came down with a crash.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

Herpes facialis in diphtheria.—Rolleston (*Brit. Journ. of Dermatology*, November, 1907) reports the result of his investigation into the frequency of this condition, based on 1,370 cases of true diphtheria under his care during the last five years He found herpes labialis present in fifty-five cases, or 4.01 per cent. Orsi, who analysed 2,400 cases in Mya's clinic, found herpes facialis present in 2.45 per cent. of the cases. Rolleston has found that herpes increased in frequency till the twentieth year of age, and that both sexes were almost equally affected. He also found the condition much more frequently present during the colder months of the year. The occurrence of herpes labialis in over 4 per cent. of cases of diphtheria completely disproves the idea, which was at one time held, that the presence of herpes on the lips was proof that the concomitant angina was not diphtheritic, even though the condition is much more common, 13.1 per cent., in non-diphtheritic angina. Herpes zoster was found in only two of Rolleston's cases. In this respect diphtheria resembles pneumonia. In pneumonia herpes labialis occurs in about 40 per cent. of the cases, but herpes zoster is very rare. Sanné and Baginski both think that the presence of herpes facialis is of no prognostic value in cases of diphtheria, as it occurs equally in the mild and severe cases. Orsi, on the other hand, regards it as a favourable sign, as all but two in his fifty-nine cases recovered. In Rolleston's series of cases the herpes was considerably more common in the severe than in the mild cases. K.

Hæmorrhages in Bright's Disease.—Riesman (*Amer. Journ. Med. Sciences*, November, 1907) discusses the various forms of hæmorrhage which may occur in Bright's disease, and reports two cases in which a true hæmorrhagic diathesis existed. The first was a male, aged thirty years, who had had two previous attacks of nephritis. On admission to hospital it was found that his urine contained 0.15 per cent. of albumen, with numerous granular and hyaline casts and blood corpuscles. Three days later hæmorrhage from the mucous membrane of the mouth set in, and was followed by extensive subcutaneous hæmorrhages. The patient died eleven days after admission to the hospital. The second case was a man, aged 55 years, who had suffered from hæmorrhages for some weeks before admission to hospital. These hæmorrhages continued, and the patient died eight days later from uræmia. Riesman suggests that while ordinary hæmorrhages in nephritis are due to the hypertension and arterial disease, these conditions are not in themselves sufficient to cause the hæmorrhagic diathesis. This condition he attributes to a toxin which resembles the hæmorrhagins of snake venom. Recently Friedeman has found in the pancreatic juice a hæmolysin capable of causing hæmorrhages. This, in normal health, is apparently neutralised by some protective substance, but under certain conditions, among which may be Bright's disease, this protective substance fails to act, and the hæmorrhagic diathesis results. Riesman looks on this complication of nephritis as of particularly bad prognostic significance. K.

Paroxysmal Tachycardia.—Schmoll (*Amer. Journ. Med. Sciences*, November, 1907) based his study of this condition on nine cases which he details, and from which he concludes that the condition is not a single pathological entity. He divides the cases into the following four groups: (1) Cases occurring in patients with a previously damaged heart, (2) cases in patients affected by dysthyreosis, (3) cases in patients exhibiting central nervous lesions, and (4) cases of apparently functional character, the so-called idiopathic group. In the first group the heart lesion alone does not cause the symptom complex, which only originates when a new weakening influence interferes with the action of the heart. In a damaged heart with weak cardiac muscle the slightest provocation may cause an attack, but in fully compensated heart disease an attack does not occur. As regards the second group, Schmoll has seen one case of paroxysmal tachycardia in a patient with adiposis dolorosa, and refers to several observations of cases in which paroxysmal attacks complicated an exophthalmic goitre. Many observations have been recorded in recent years, showing the connection between various lesions of the central nervous system and paroxysmal tachycardia. Thus the condition has been observed in tabes, in multiple sclerosis, in tumour of the brain, and lesion of the medulla oblongata. Schlesinger has observed epilepsy in 25 per cent. of his cases, but all these cases belonged to the symptomatic group of epilepsy caused by anatomical lesions. Schlesinger also records a very interesting case, in which inflammation of the right vagus was discovered post mortem. In this case the attacks could be at once stopped by compression of the right vagus, while compression of the left vagus did not appear to influence the attack. In the fourth group are cases in which no anatomical lesion can be discovered, and which resemble the so-called functional epilepsy to which condition paroxysmal tachycardia has many analogies. The mechanism of the attacks is illustrated by tracings taken during the paroxysms. K.

Diagnosis of Syphilitic Heart Diseases.—Herzog writes on the above subject, and calls attention to the great importance of early diagnosis, though he admits the difficulty presented by these cases (*Berlin Klin. Woch.*, 1907. No. 31). Increased blood pressure accentuated aortic second sound, heaving and diffuse impulse, with irregularity of rhythm, and the pressure of Mussel's phenomenon (nodding of the head synchronous with the pulse) all point to disease of the aortic and coronary arteries, and when there is a syphilitic history, are of special significance. Potassium iodide and mercurials are often of great value in these cases. Another striking characteristic is a rapid development of symptoms, and the appearance of nervous palpitations in patients who are in no way neurasthenic. Aortic insufficiency occurring in middle life, in persons who have no rheumatic history, is also often a syphilitic phenomenon. M.

Erythema Nodosum.—Langford Symes calls attention to the possible infectious nature of this disease (*British Journal of Children's Diseases*, July, 1907). He has lately observed many cases which suggest that such may be the case. Most of those who suffered were together in the same hospital, and he noted multiple cases in houses. The disease set in in every case with pronounced febrile symptoms, and in one case a systolic murmur developed, which however disappeared during convalescence. The writer moreover has at times observed erythema nodosum as a preliminary symptom in cases of meningitis, and therefore believes that it should in all cases be regarded more seriously than is usually the case. M.

Opthalmoscopic Appearances in Vaquez Disease.—Jackson has carefully studied the conditions of the eye in a case of chronic cyanotic polycythæmia (*Opthalmology*, October, 1907). The patient, who suffered from extreme cyanosis, and whose blood count showed the presence of over nine million red cells per c.m., came complaining of blurring of sight, and of epiphora. Examination with the opthalmoscope showed that the dioptic media were clear, but that the retinal veins were large, dark, and tortuous, and about double the size of the arteries, which last-named vessels appeared normal. Later it was found that the pupils were unequal, and did not react well to light, and that some retinal hæmorrhages had appeared. These hæmorrhages were not flame shaped, but were rounded with faintly shaded borders. No white spots were seen, and no other fudal changes. The above observations agree with what has previously been noted in any of these cases that were subjected to proper examination. M.

The Relation of Intestinal Infection to Visceral Tuberculosis.—Whipple, as the result of previously recorded work, has come to the conclusion that the intestinal tract does not play an important rôle as a portal for the entry of tubercle bacilli into the various organs of the body. He now amplifies this work by an analysis of several new cases, and by experiments carried out on animals. He formulates his conclusions as follows: The tubercle bacillus can not pass from the intestine through the lacteals, mesenteric glands, and thoracic duct, into the lungs, without leaving some record of such passage. A few bacilli may, under favourable circumstances, be swept along this course to the lungs, but the majority surely will lodge in the glands, and in time cause a tuberculous process, which can be recognised. When the mesenteric glands are not involved we may exclude the intestinal tract as the portal of entry, but the converse does not hold for the tuberculous mesenteric glands, which may be secondary to some pulmonary forms that are discharging tubercle bacilli into the alimentary tract. The thoracic duct is often the distributing agent in cases that show scattered tubercles in the viscera and tuberculous mesenteric glands.

M.

Treatment of Tuberculous Peritonitis.—Bussi (*Gazz. deg. Ospedali Milan*, September, 1907) relates a number of instances in which he was able to cure the patient by medical measures alone, tapping the effusion and painting the abdomen with iodine and guaiacol, supplemented by hypodermic injection of a solution of 1 gm. of iodine to 10 gm. potassium iodide, with 20 gm. guaiacol and 80 gm. glycerine; in some cases an iodised gelatine preparation was given by the mouth later. The results were good in all the cases related. He ascribes almost a specific action to iodine in tuberculous affections. In one severe case recovery followed tapping and insufflation of heated air into the abdominal cavity, supplemented by a compressing bandage and administration of iodised gelatine. In another very severe case, in a girl of 16, no benefit was derived from medical measures, and the peritoneum was drained and wiped dry. Typical tuberculous granulations were found disseminated over the peritoneum and intestines. After the abdomen was sutured the iodine and guaiacol applications were resumed, with prompt recovery to date, a year later.

D.

Treatment of Acute Articular Rheumatism with Constriction Hyperæmia.—Steinitz (*Zeib. f. Klin. Med. Berlin*, 1907) reports his experiences with 175 patients treated by constriction hyperæmia with and without the salicylates. The application of the constricting band almost invariably relieved the pain. A large number of patients recovered in from 4 to 20 days, as early as those treated with the salicylates. Even if the Bier treatment fails to cure, it can scarcely ever do harm. Complications seemed less frequent and milder than under exclusive salicylic medication. High temperature does not contra-indicate it. In case moderate temperature persists unmodified after the fifth day under the Bier treatment, he advises giving salicylates, as also when the affection changes rapidly from joint to joint. In cases of recent endocarditis, he advises restricting the salicylates as much as possible and relying mainly on the constricting band. D.

Hysterical Sweating.—Curschman (*Mün. Med. Woch.*, September, 1907) reports two cases of long-continued periodic sweating in a mother and daughter. They appeared two or three times daily, were of a drenching character, unaccompanied by chill or by fever, and without any preceding hysterical manifestations (convulsions, etc.). During the attack the mind was clear, the patient quiet and peaceful, no preceding embarrassment or excitement was demonstrable. The sweats presented the picture of those resulting from the use of diaphoretics. Blood pressure and frequency of pulse were never increased. No organic changes in the central nervous system could be made out. Treatment by suggestion proved promptly effective in both cases. The author considers the etiology to have been hysterical. He has found no similar cases reported in the literature. D.

Apomorphin in Diagnosis of Bulbar Affections.—Ferreira (*Presse Med. Paris*, September, 1907) announces that a weak or negative response to a small test injection of apomorphin will reveal bulbar paresis before it is clinically manifested. Glossolabial-laryngeal paralysis can thus be detected in its incipiency by the degree of nausea and the amount of vomiting. If there is no vomiting at all, the medulla oblongata is already seriously affected. D.

Nasal Origin of Lupus of Face.—Caboche (*Presse Med. Paris*, October, 1907) presents an array of evidence to sustain his assertion that lupus of the face, in nearly every case, is the result of the propagation to the skin, by way of the lymphatics, of a lupous lesion on the nasal mucosa. Treatment of the latter alone is sometimes followed by the retrogression of the superficial lupus, and inversely if the latter is treated alone, there is liable to be re-inoculation from the nasal lesion. D.

Diagnosis and Treatment of Tuberculous Skin Affections.—Nagelschmidt (*Deut. Med. Woch.*, Berlin, October, 1907) relates that a drop of tuberculin inoculated into a tuberculous lesion of the skin causes ulceration. Inoculation of sound skin causes the development of a papule, but no ulceration. He has found this an excellent means of determining whether a lupous patch has entirely healed under Finsen treatment, or whether there are still some points left, especially those embedded in cicatricial tissue which it is difficult for the Finsen rays to reach. The inoculation has not only diagnostic value, but also a direct curative action, as the nodules heal definitely under the influence of the transient ulceration. Minimal quantities of tuberculin suffice for the reaction. He deposits two or three drops of tuberculin around the lesion, and scrapes the skin between them. After 15 or 20 seconds he wipes off the tuberculin without touching the excoriated part. This avoids absorption of superfluous tuberculin, and prevents any general reaction. Sometimes he injects a drop of tuberculin directly into the nodule. He commends this local tuberculin treatment for lupus when Finsen treatment is not accessible, especially for isolated foci, also for differentiation of tuberculous cutaneous affections, and as supplementary to other methods of treatment. Its drawbacks are the loss of substance left by the ulceration and the liability to a general reaction if too much tuberculin is absorbed. D.

Gift for Cripples.

At a meeting in connection with the Birmingham Crippled Children's Union on November 23, a communication from Mr. George Cadbury, offering the Woodlands, a large residence standing in four acres of ground at Northfield, as a convalescent home for child cripples, was considered. A resolution was passed accepting the gift, and thanking Mr. Cadbury for his munificence. It was stated that the house, which contains fifty rooms, had been inspected by the medical officers of the Union, who were entirely satisfied as to its suitability for the purpose to which it is now to be devoted. It will accommodate forty children. The site adjoins the Bournville Village Trust property, so that the maintenance of healthy surroundings is assured. It is in contemplation to hand the Woodlands over to the Birmingham Corporation, but this is left to the discretion of the committee of the Crippled Children's Union.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Post-Graduate (London).—In all cases of malignant disease the blood should be examined as a matter of routine. But upon this point our correspondent had better communicate with Dr. John A. Shaw-Mackenzie, who, no doubt, would supply all the information required. Dr. Shaw-Mackenzie was the first to show the value of this method of examination in cases of the kind.

X. Y. Z.—The case is obviously one in which the medical man concerned should be summoned to give evidence. But coroners in rural districts are often disposed to ignore this necessary detail, presumably for the purpose of saving the fees.

Tu quoque.—We have carefully considered our correspondent's communication, and our advice to him is to leave the matter alone.

ANATOMICAL QUESTIONS AND ANSWERS.

The Professor: Some of you gentlemen are not giving me your closest attention. Mr. Biggs, what do we find under the kidneys?

Future M.D.: Toast, sir.

Dr. Gaskell.—The expression "courir comme un derate" is derived from the belief (founded, we are assured, on actual practice) that persons whose spleen has been removed are able to run better than their brethren who are still burdened with this viscus. The operation is not a recognised surgical procedure, at any rate, for purely athletic purposes.

M. R. F.—Bier's method of treatment by provoking a determination of blood to, or its stasis in, a given part is applicable to boils and carbuncles, and gives very good results. In a sense, of course, the historical practice of sucking a poisoned wound may be said to act somewhat in the same way, though the action must be in a measure mechanical, the blood washing away the poison.

Dr. Lionel Tayler.—Your letter has been forwarded to "Paterfamilias Medicus" for reply.

Meetings of the Societies, Lectures, &c.

Wednesday, December 4th.

Royal Society of Medicine (Neurological Section) (20 Hanover Square, W.).—8.30 p.m.: Papers:—Dr. J. S. Collins: On Certain Peculiarities of Intra-cranial Gummata.—Dr. F. E. Batten and Dr. G. Holmes: Nervous System of a Dog with Ataxia. Dr. T. G. Stewart: Four Cases of Tumour of the Fourth Ventricle.—Dr. E. F. Buzzard: Case of Tubercle of the Sixth Nucleus.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. C. Ryall: Clinique. (Surgical.) 5.15 p.m.: Lecture.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Thursday, December 5th.

North-East London Clinical Society (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Clinical Cases.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. J. Berry: The Treatment of Hip Disease in its Later Stages.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Fungous Diseases of the Hair: I., Hyphogenic Sycosis; II., Tinea.

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Batten: The Treatment of Infantile Paralysis.

Friday, December 6th.

Royal Society of Medicine (Laryngological Section) (20 Hanover Square, W.).—5 p.m.: Cases and Specimens will be exhibited by Dr. C. Potter, Dr. J. Horne, Mr. A. Evans, Mr. H. Tilley, and Mr. H. Barwell.

West Kent Medico-Chirurgical Society (Miller Hospital, Greenwich, S.E.).—8.45 p.m.: Purvis Oration: Dr. R. Russell: The Diagnosis of Organic from Functional Affections of the Nervous System. Conversazione.

West London Medico-Chirurgical Society (West London Hospital, Hammersmith Road, W.).—8.30 p.m.: Papers:—Dr. M. Moullin: Treatment of Uterine Fibroids.—Mr. S. Headley: Chronic Appendicitis in Women.

Child Study Society (Parkes Museum, Margaret Street, W.).—8 p.m.: Lecture:—Prof. J. Edgar: Imitation and Individuality in Children.

Society of Anæsthetists (20 Hanover Square, W.).—8.30 p.m.: Paper:—Dr. W. J. McCardie: Status Lymphaticus. Adjourned Discussion on Mr. H. Hilliard's paper.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. R. Lake: Clinique. (Ear.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Saturday, December 7th.

Royal Society of Medicine (Otological Section) (20 Hanover Square, W.).—10 a.m.: Cases, etc., will be shown by Mr. S. Scott, Mr. A. H. Cheatle, Mr. H. Tod, Mr. R. Lake, Mr. M. Yearsley, Dr. W. Milligan, Mr. L. A. Lawrence, and Dr. W. H. Kelson.

Appointments.

McRae, G. Douglas, M.D., F.R.C.P.E., has been appointed Medical Superintendent to the Ayr District Asylum.

Bunch, J. L., M.D., B.S.Lond., Physician in Charge of the Skin Department at the North-Eastern Hospital for Children.

Clarke, H. M., M.B., B.C.Camb., Clinical Assistant to St. John's Hospital for Diseases of the Skin.

Friend, G. E., M.R.C.S., L.R.C.P.Lond., Clinical Assistant to the Chelsea Hospital for Women.

Griffith, T. Wardrop, M.D.Aberd., Honorary Consulting Physician to the Leeds Public Dispensary.

Michie, W. A., M.D.Aberd., M.R.C.S.Eng., Clinical Assistant to St. John's Hospital for Diseases of the Skin.

Morton, John, M.B., M.S.Glasg., Clinical Assistant to the Chelsea Hospital for Women.

Tylecote, F. E., M.D.Vict., M.R.C.P.Lond., Clinical Assistant to St. John's Hospital for Diseases of the Skin.

Vacancies.

Seamen's Hospital Society, Greenwich, S.E.—Medical Superintendent of the Dreadnought Hospital, Greenwich. Salary £200 per annum, with board in the Hospital. Applications to P. Michelli, Secretary.

University of Manchester.—Senior Demonstrator in Physiology. Salary, £150 per annum. Applications to the Registrar.

Bristol General Hospital.—Senior House Surgeon. Salary, £120 per annum, with board, residence, etc. Applications to the Secretary.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Resident Medical Officer. Salary, £100 per annum, with board, apartments, washing, and railway contract. Applications to C. W. Hunt, Secretary, Hardman Street, Deansgate, Manchester.

Wandsworth Union Infirmary, St. John's Hill, near Clapham Junction.—Junior Assistant Medical Officer. Salary, £100 a year, board, lodging, and washing. Applications to the Medical Superintendent.

The Homes for Little Boys, Farningham and Swanley, Kent.—Medical Officer. Salary, £100 per annum, with board, residence, and laundry provided. Applications to Percy Roberts, Secretary, Homes for Little Boys, 100, Temple Chambers, Temple Avenue, E.C.

Births.

Gavin.—On Nov. 26th, at 61, Biddulph Mansions, Elgin Avenue, London, Evelyn, the wife of A. C. Gavin, M.B., of a son.

Tebb.—On Nov. 25th, at 226, Finchley Road, Hampstead, Bertha Mary, the wife of Albert Edward Tebb, M.D., of a son.

Marriages.

Burleigh—Wallace.—On Nov. 20th, at Glasgow, James Seath Burleigh to Edith Christine Wallace, M.D., daughter of the Rev. James Wallace, Church of Scotland, Glasgow.

Robertson—Tooley.—On Nov. 28th, at Mombasa Cathedral. East Africa, Alexander Robertson, M.B., C.H.B., D.S.H., of Elgin, N.B., to Gertrude Emilie, third daughter of Mark Tooley, Esq., Denmark Hill, London.

Deaths.

Hooper.—On Nov. 24th, at 9, Trinity Square, Borough, Daniel Hooper, B.A., M.B., London, for many years physician to the Surrey and Clare Market Dispensaries, in the 85th year of his age.

Laird.—On Nov. 27th, at 58, Salcott Road, Wandsworth Common, Elizabeth Ann Laird, widow of the late James Laird, M.D., R.N., aged 82 years.

Porter.—On Nov. 27th, at Salisbury Road, Southsea, Mary J. R. Porter, widow of Surgeon-Major J. H. Porter, A.M.D.

Woodford.—On Nov. 27th, at 67, Eardley Crescent, London, Jessie Jane, widow of the late C. T. O. Woodford (M.D., F.R.C.S.London), of Calcutta, aged 75.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, DEC. 11, 1907. No. 24.

NOTES AND COMMENTS.

G.M.C. and Penal Powers.

THE recent proceedings of the General Medical Council meeting bring out into relief the fact, which has long been patent to those interested in the doings of the Council, that that body is badly equipped in the matter of penal powers. It has, in fact, but one power, namely, that of striking a medical man off the Register. So inelastic and clumsy is this instrument of discipline, that in course of time the Council have evolved various devices for using it with less than full force. For instance, a culprit in whose case there are extenuating circumstances may be told that judgment will be delivered next session, a course which gives him the opportunity of reform in the meanwhile; or an accused may be summoned to appear in person before the Council, a course which may mean the loss of some days' work and a good many incidental expenses. But, still the point remains that the inability to mete out different specific degrees of punishment is a serious handicap to the administration of justice and the maintenance of discipline. It is a gross anomaly that the man who has been convicted of procuring criminal abortion and a man who has been fined five shillings for a trivial offence should both be subjected, or be liable to be subjected, to the same penalty, namely, striking off the Register. It will be argued that serious crimes are dealt with by the law, and therefore the General Medical Council merely has to strike offenders automatically off the list after their conviction, but the point remains that in any future Bill dealing with the Council the power should be sought for ability to grade penalties. A power to fine a medical man £50 or £100 would be most useful in the case of civil offences of a minor character, and would not be so severe a punishment as completely striking him off the Register.

Value of Representation.

IN the present state of the law at any rate, everything should be done which can properly be done to keep a man on the Register, because while he is still there he is under some kind of discipline and control, whereas if he be struck off, as likely as not he has no alternative to his profession whereby to earn his living, and his uncontrolled practice goes on. On the other hand, if the Council had power to impose a heavy fine, and to repeat it if necessary, the proper conduct of the offender's practice would be more effectively ensured. Diversified powers of this kind are badly needed, and now that the Council are beginning to awaken to the fact that there is a body of men called general practitioners which has many grievances and trials, we hope they will seriously set themselves to work to think how they may best reform their own constitution and powers. The fresh blood infused into their veins by the new direct representatives has had an oxygenating effect already, and the rank and file of the profession will not be slow to recognise the result and the credit its authors deserve. Perhaps in the future, when the General Medical Council is like that of other professional bodies, namely, representative of the profession it is supposed to represent, it might be possible to affect the members directly by the feelings and opinions current at the time.

Anti-Quackery Legislation in New Zealand.

THE Bill for the prevention of quackery in New Zealand is before the House of Representatives, and has reached a very exciting stage, namely, that which follows the report of a Parliamentary Committee. It will be remembered that the Bill was violently opposed not only by the traders in quack drugs, but by the newspaper interest generally. Indeed, the storm raised by the latter threatened to engulph the infant at its birth. However, so far it has survived, although the Committee have toned it down a good deal, in form at any rate. The gist of the matter is the disclosure of the formula, which, of course, is diametrically opposed to the interests of the trade, because not only are the formulae of these preparations utterly devoid of originality, but they command their sale by working on the awe and superstition of people. The committee have given in on this point to the extent of providing that a formula need not be disclosed if it is original, and the proprietors can satisfy the High Court that it is not fraudulent or harmful, that it is by way of doing what it claims to do, and that it may with safety be entrusted to inexperienced and uninformed persons for the purpose of self-treatment.

Further Recommendations.

IF the authority to which reference as to the character of the preparation is to be made had been the medical council of the Colony, which should surely be better able to form an opinion on the effect of drugs than the High Court, this proviso would not be very much of a hindrance to good administration, but it is obviously a great experiment to make the High Court the arbiter, for the questions raised would not be legal in any sense, and no one can predict how they would present themselves to a lawyer's mind. Still, on the whole, the provision ought not to spoil the Bill, for even if it did not work quite equitably in practice, there are other valuable provisions, such as that measures should be taken to stop the sale and advertisement of all preparations and medicines which do not comply with the regulations just mentioned. The committee urge the Government to put the matter through this session, and we hope indeed they will If the measure can be carried now while the ma is alive it will have far more effect than if it is allowed to drivel through session after session, continually being watered down by the trade and the papers. Now, if New Zealand carries this legislation through, we take it that three-quarters of the patent medicine trade will be done away with, and that the quarter that remains will be emasculated, so far as its powers for harming people are concerned. New Zealand, too, is the most democratic country in the world, and it is a bitter lesson of the power of interest over the good of the community that all the advantages of experience and intellect which the mother country enjoys do not enable her to tackle a simple question of this type.

"The School of Brutality."

THE unfortunate incidents connected with the "Brown Dog" have had the effect which we feared, namely, the opening of the vials of antivivisection vituperation on medical students. Under the title of "The School of Brutality," Miss Lind-af-Hageby, the lady whose incorrect statements—to use the language of courtesy—let Mr. Coleridge in for his slander action and an adverse verdict of £2,000, has published a collection of cuttings about the disturbances, preceded by a waspish introduction by herself. This is being circulated with the announcement of a lecture by herself on "Vivisection and Medical Students," and therefore it may be guessed what the character of the lecture will be. Miss Hageby, having laid the train, lighted the fuse, and seen the building explode, now has the exquisite pleasure of talking to her friends and rubbing her hands over the effects of the explosion. We hope that in common honesty Miss Hageby will explain the part she took in igniting the flames and the mechanism of the Coleridge action.

Drink "Cures."

A SIGNIFICANT light was thrown on the composition of the Royal Commission on Quackery—when it does come, as come it must sooner or later—by the reply made by the Home Secretary to a temperance deputation that waited on him the other day. Mr. Gladstone said that he recognised that the 1898 Act for controlling inebriety had been to a great extent a failure, and that he would appoint a departmental committee to inquire into the question of inebriety and narcomania. In the meantime he would await the report of the Royal Commission on Feeble-mindedness, which is shortly to be issued, because it will contain a large amount of evidence as to drunkenness, and certain recommendations for legislation might be made. He then proceeded to discuss the composition of the Departmental Committee, and expressed the opinion that the medical element should be adequate, but subordinate to the lay. Mr. Gladstone indicated that drink "cures" would be one of the matters specifically referred to the committee, because of the number that have appeared on the market of late, and the interest shown by the public in them. Now, we should have thought that in a matter so technical as this medical men would have been the only people whose opinion was worth having, and that if laymen were appointed they should be but few proportionately. However, the view of the Home Office is different, and they have the deciding voice. At any rate, we offer a warm welcome to such an inquiry.

LEADING ARTICLES.

LONDON UNIVERSITY CRISIS.

IT is now almost a hundred years since the University of London entered on the most chequered career that ever University pursued. Almost from its birth the academical institution of the hub of the Empire has been in the throes of construction or reconstruction, with the result that after a century of tinkering it remains a monument of the inefficiency of Londoners to manage educational affairs. If the cause of the fiasco be sought, it will be found to consist of several complex factors, such for instance as a lack of civic patriotism in Londoners, in a contempt for education which distinguishes many commercial minds, and above all perhaps, in a want of idealism. Still, there is no gainsaying the fact that the University of London is as little interwoven with London life as is the University of Brussels. This aloofness is found not only in medicine, indeed perhaps is seen less in medicine than in any other faculty, but is to be found in arts, science, law, and music. Indeed, the London University, instead of being an expression of the civic ardour for culture, is like the "foreign garrison" in Ireland, a kind of extraneous authority placed over the heads of the natives to see that too much freedom and independence does not exhibit itself. We have only to compare these university methods with those in Scotland to see exactly where failure occurs. In Scotland the elementary school lad, if he is able to go on with his studies, passes naturally to the intermediate school, and from the intermediate school to the university, where after an average career he finds himself M.A. in two or three years. That is to say, the university caters for the average man, provides him with his progressive scale and the means to mount it, and ends by conferring on him the *cachet* of M.A., because that degree is a commercial asset wherever he goes for a job. The London University takes no notice of its students till they come to it, and then insists on their passing an examination which would pretty nearly win them a university degree in Scotland. Although London has lately assumed teaching functions, these are yet pretty far divorced from the examining ones, which remain the prime object of the system. The students are sent up for exceedingly difficult examinations, and a comparatively small proportion are passed; whilst it has been recognised for years that the examinations are "tricky." Indeed, when the object of an examination is rather to keep candidates from a degree than to provide a gateway to it, the "tricky" element is bound to appear. The consequence of this throttling policy is that the London University is an ogre to London students instead being the friend that helps to success, and it is distinctly understood that the desire of the authorities is that only a small proportion of the students are to be eventually successful in graduating. Now, this same principle holds good in the London University attitude towards medical students. Instead of all students going in for the London M.D., and about 75 per cent. being successful, about 30 per cent. or so go in, and about 15 per cent. or so eventually attain it. The London University may, and does, demand a high standard for its degrees, but as a University for London it has completely failed. It is a mere geographical accident that it happens to be situated in the Metropolis. The last scene of all in this strange, eventful history is the recent ruination of the work of that band of devoted reformers who, largely under the inspiration of Dr. Kingston Fowler, nearly succeeded seven years ago in adapting the university to the needs of the teeming millions in London. The work we are specially concerned with is that of medical education. When the university was reconstructed in 1900, and "internal" students created, it was obvious, not only for the sake of economy for the medical schools but for the creation of the "University" idea, that a centre of teaching should be established. The elementary medical subjects needed such united teaching, schemes was made out and approved, funds were appealed for and in part promised, a splendid site was granted, and everything was ready for the university to go ahead, when the old prejudices, prepossessions and vested interests, surged into force again, and the scheme was defeated. The Senate of the University has consequently given up the site, and purposes to send the money back to the donors, and the hands of the clock are put back for another twenty or thirty years. The history of the London University is a string of ineptitudes, of which the last item is perhaps the greatest. Londoners and lovers of culture can only hope that God does not slay all those whom he drives mad.

CURRENT TOPICS.

Mountain Sickness.

DR. W. H. WORKMAN, in the course of a lecture recently delivered before the Royal Geographical Society, gave an interesting account of his climbing experiences in the Nun Kun group in Kashmir. He dealt particularly with the glaciers, and notably with the *niveos penetrantes*, which he met with for the first time in five seasons of Himalayan exploration. An interesting part of his paper to all mountaineers is that connected with mountain sickness. Dr. and Mrs. Workman stayed one night alone at a camp 21,300ft. above sea level, the highest point, up to the present, at which mountaineers had passed the night. There were nine Europeans—a guide and six porters, with the two heads of the expedition —and only one porter really suffered from mountain sickness. "Although complaining of headache and weakness," said Dr. Workman, "at the third camp (20,632ft.), he started to go to the fourth with a light load of instruments, but was unable to keep up with the rest of us, and soon fell behind, showing unmistakable signs of mountain sickness. Before reaching an altitude of 21,000ft., though naturally a strong and healthy man, he collapsed entirely and became helpless. He complained of loss of sensation in his hands. His woollen mittens being drawn off, his fingers were found white and stiff, and if not already frostbitten on the point of becoming so. Vigorous rubbing and pounding of his hands finally restored circulation, when he was sent down to the third camp. The fact that his hands, even when protected by thick woollen mittens, were brought by the cold to the verge of frostbite, while my own, without any covering, were comfortably warm, shows how profoundly the circulation and vitality are prostrated by mountain sickness, and how dangerous it is for one suffering from this malady to be exposed to the cold of high altitudes." None of the other members of the party were incapacitated, but, said Dr. Workman further, "Every one, as was to be expected, felt the effect of altitude on the respiration, though some to a greater extent than the others. This, as is usual, manifested itself by shortness of breath and panting on slight exertion. In the erect position, when resting, the respiratory disturbance was not so noticeable, being marked only on movement, but at night on lying down it became more urgent, being accompanied by a feeling of oppression, for the relief of which a number of deep inspirations were necessary. The frequent repetition of these wearied the respiratory muscles and even became painful. During the five nights at our three highest camps no one obtained more than a few snatches of sleep, and four, of whom I was one, practically none at all. It is scarcely necessary to say that even the strongest could not hold out for long against the depressing influence of loss of sleep, combined with the lowering of vital energy due to the scarcity of oxygen at these high altitudes."

Candour between Physician and Patient.

IN an address to the Medical Society of the State of New York, a week or two ago, ex-President Cleveland put in a plea for greater candour on the part of the medical attendant toward his patient. According to Mr. Cleveland, a critic friendly to the profession, the medical man still likes to maintain a certain air of mystery as to the means by which he works, and is loath to give the patient any information as to the methods employed in curing his disease. In the past there certainly was this tendency on the part of the physician, who cloaked his ignorance in learned words, and others beside Mr. Cleveland charge us with it at present. There is no doubt that in all cases there should be perfect frankness so far as the intelligence of the patient will permit, and it is astonishing how much further this is than many medical men imagine. Moreover, in many cases the curative effect of the physician's labours may be materially increased by obtaining the intelligent co-operation of the patient. The physician should proceed, not by Eddyist hocus-pocus, but by measures whose rationale he should be able and eager to explain.

Victory at Cheltenham.

WE have had occasion before to refer to the case of Dr. J. H. Garrett, Medical Officer of Health for Cheltenham, whose services a section of the Council of that town proposed to reduce from £600 to £500 a year. Last week the matter came before the Town Council, the Health Committee bringing forward a report against the decrease in reply to one in its favour presented by the Expenditure Inquiry Committee. Alderman Norman, who moved the adoption of the Public Health Committee's report, said that probably the Council were unaware that the Local Government Board had controlling power in that matter, and that it was exceedingly improbable that they would consent to the decrease, as £500 was the minimum recognised by the Board for a town of the size of Cheltenham, and, moreover, that Dr. Garrett had put in six years' good service since the increase was granted. Alderman Skillicorne, who moved an amendment, said that

Dr. Garrett had "insulted" members of the Council, and that if they did not decrease his salary they would be laying themselves open to be similarly insulted by all their officers. Now, Dr. Garrett had previously shown that the "insult" consisted in putting a wrong interpretation on his words, and it seems that the councillors who felt themselves insulted must have had very tender consciences. The Health Committee, who were certainly in the best position to judge of Dr. Garrett's work, were in his favour; and a medical member of the Council said that no sort of case had been made out for reducing the salary, but that the Inquiry Committee, failing to find anything wrong anywhere else in the various departments, pitched on the medical officer's salary. When it came to voting, the amendment was only defeated by the narrow margin of eleven votes to ten, and the Health Committee's report was adopted by a majority of twelve to nine. We sincerely congratulate Dr. Garrett on his well-earned success. Fortunately, matters at Cheltenham did not come to the pitch they arrived at at Southend, but they were near enough to be uncomfortable. At any rate, the same solidarity might have been looked for in the profession if the crisis had been brought about.

Town Water Supplies.

The rapid growth of the great centres of population renders the problem of the national water supply one of increasing difficulty. Many of the rivers have been drawn upon to the extent of their capacity consistent with the maintenance of their own streams. Moreover, as the rural and provincial density increases, the inevitable resulting pollution of rivers makes them more and more undesirable for potable purposes, so that the cities are driven to the great watersheds and mountainous districts for their supplies. The whole question, so far as London is concerned, must became a matter of urgency before many years have passed away. The Metropolitan Water Board is at present discussing the momentous question as to the desirability of securing an additional water supply for Londoners, "after increased supplies from the Thames are no longer economically available." Sooner or later it seems probable that they will have to resort to the Welsh mountains for their catchment area. The *Standard* has advocated the widening of their scheme of operations so as to secure a national basis. There is a good deal to be said in favour of that proposal, for water is just as much a necessity of life as air or earth. So long ago as 1869 the Royal Commission, presided over by the Duke of Richmond and Gordon, recognised the necessity of parliamentary interference in order to prevent the selfish appropriation of watersheds by local authorities. It is tolerably clear that Londoners have been caught napping, and have been to a great measure forestalled in the matter of the Welsh hills. Under any circumstances, however, it is unlikely that a more enlightened generation will consent to drink river water that has been extensively polluted with sewage.

Civilian Doctors and Army Medical Training.

We are informed by the War Office that, in order to utilise the valuable clinical field provided by the Queen Alexandra's Military Hospital, the Army Council have decided to associate that hospital with the Royal Army Medical College, as an integral part of its medical school, for the purpose of furthering the earlier and advanced education of officers of the Royal Army Medical Corps. They have further decided to obtain the assistance of certain prominent members of the medical profession as consultants in medicine and surgery, whose professional skill will conduce to the efficiency of the hospitals as regards both the treatment of the sick and the investigation of the various diseases incidental to military life. These appointments will have the further effect of fostering among the civil members of the profession a greater interest in the work of the Army Medical Service, and in those special problems with which its officers have to deal.

The following appointments have been approved:

To be Consulting Surgeons:—

A. E. Barker, Esq., F.R.C.S., Professor of Surgery, University College of London.

A. A. Bowlby, Esq., C.M.G., F.R.C.S., Surgeon to St. Bartholomew's Hospital; and

G. H. Makins, Esq., C.B., F.R.C.S., Surgeon to St. Thomas's Hospital.

To be Consulting Physicians:—

Dr. J. Mitchell Bruce, F.R.C.P., Consulting Physician Charing Cross Hospital.

Dr. J. Kingston Fowler, F.R.C.P., Physician to Middlesex Hospital.

Dr. W. Osler, F.R.S., F.R.C.P., Regius Professor of Medicine, University of Oxford.

Medical Examination of Children for Factory Work.

A school attendance officer has written a pertinent letter to the *Manchester Guardian* on the medical examination to which children and young persons are subjected before being permitted to enter the factory or workshop. The journal in question makes some sensible comments on the communication, and endorses generally the sceptical attitude of its correspondent. Out of 700 children who have in the latter's experience been allowed by the education authorities certificates of practical and complete exemption from school attendance, only one, to his knowledge, has been declared fit by the certifying surgeon to work in the mill. Obviously, if these children were unfit to attend school, they were not proper candidates for factory life. The last report of the Chief Factory Inspector shows that, out of a total of 390,829 examinations, there were only 3,257 rejected on medical grounds, or three-quarters per cent., a result that certainly does not justify the pessimists who talk in so dejected a way about our physical degeneration as a nation. In 1906 only 800 conditional certificates were given—that is to say, restricting the child to certain occupations. It is hard to think that out of 390,829 children all except 800 were fitted for all and every kind of work. Among the 800, moreover, were cases of infantile paralysis, hip and spinal disease, epilepsy, heart disease, phthisis, bronchitis, and scrofula. It is no excuse for the certifying surgeons that the fee for examination is absurdly inadequate, and that in the case of rejection their reasons must be stated in writing. If the duty be accepted by the certifying surgeons, it should clearly be performed with a full sense of responsibil[illegible]y. On the other hand, it is clear that a rigid examination and a high standard would make demands upon the surgeon's time out of all proportion to the emoluments. If the Government of this country are in earnest in their desire to exclude diseased and feeble children from our factories and workshops, they will do well to attend to this serious defect in industrial legislation.

The Irish University Question.

The most important announcement on this subject was made on Thursday last at Manchester, when the Provost of Trinity College announced that he had received positive assurances from Mr Birrell that, in the proposals which he hopes to lay before Parliament, Trinity College, its constitution, and its endowments are absolutely excluded. The Provost further announced that the governing body of Trinity College would be prepared to give Mr. Birrell every assistance in their power in working out any scheme for the real good of the country. We cordially congratulate both Mr. Birrell and the Provost, the former because he has decided to work in the path of the least resistance, rather than in that of the greatest resistance, the latter because a great danger to the institution over which he presides has been averted. It was a foolish policy which led Mr. Birrell's successor to try to begin his work by felling mighty oaks across the path which he must travel to reach his end, and now that such a policy has been abandoned it is to be sincerely hoped that head-way will be made. To judge from a further statement made by the Provost, it would appear that the general lines along which Mr. Birrell intends to work are similar to those at which we have already hinted in these columns. Thus, there may be a revival in Belfast of the old Queen's University, which will have an "atmosphere" of its own decided by the majority of its students, while the remaining three Colleges will be united with another University, which will also have an "atmosphere" of its own. Like Sir Edward Carson, we prefer to see Mr. Birrell's new Bill before we express an opinion thereon, but it should follow the lines at which the Provost hints. It will, at any rate, start with a far greater prospect of success than did Mr. Bryce's happily defunct scheme.

The Nature of the Soul.

When Descartes thought fit, nearly three hundred years ago, to publish his "Discourse," in which, among other topics, he treated of the location of the soul, he was subjected to a certain amount of opprobrium in that he chose to appeal to the ignorant rather than to the learned, by couching his reasonings in the vulgar tongue. It is, therefore, in good company that Dr. Albert Wilson, "who is shortly publishing the result of his researches into the brain, which he has been carrying on for the last twenty years," addresses himself first to the unlearned, and makes the earliest disclosure of his results, not through the medium of one of the scientific journals, but in the columns of *Black and White*. He has, doubtless, been wise in his choice. Moreover, like a discreet man of business, Dr. Wilson discloses so little of the secrets he has discovered that all his readers are left agog for more information. We are told that his researches "have helped to demonstrate both the existence of the soul and the possibility and probability of its existence after death." The soul, we are told, "is a superstructure of the mind"; and the mind, being a superstructure of the brain, if not, as is suggested, the cortical layer itself, we are led to the conclusion that the soul is a superstructure on a superstructure, which, nevertheless, can exist after the disappearance of its foundation, the brain. Dr. Wilson's researches are rich in practical as well as theoretical points of interest. For instance, the "pre-frontal arc of the brain" is the seat of control, which can be put out of action by alcohol. Our whole prison system, too, is wrong, as, to quote Dr. Wilson's own words, "The antiquated law methods of so much punishment for so much crime is too fossilised to deserve any toleration." No more, alas! must the punishment fit the crime. Mr. Bernard Shaw tells us that what the poor suffer from is poverty. Not so Dr. Wilson; he finds that they suffer from deficient brain-cortex, "due to the destructive influence of enforced education."

PERSONAL.

H.R.H. Princess Christian of Schleswig-Holstein opened the new operating theatres and anæsthetising rooms at the Royal Free Hospital on December 3rd.

Mr. Francis Reckitt has given a donation of £10,000 to the Great Northern Central Hospital.

Professor Landouzy has been selected for the post of Dean to the Faculty of Medicine at Paris, in place of M. Debove (resigned).

In memory of Professor Pirogoff, the Moscow Town Council propose to name a street after him, and triennially to award a prize of £60 value for a work on Surgery.

It is announced that Professor Ronald Ross is to be invited to accept the post of Physician to the Ward for Tropical Diseases lately established at the Royal Southern Hospital, Liverpool.

The annual Bradshaw lecture was delivered before the Royal College of Surgeons on Friday last by Mr. Rickman J. Godlee, vice-president of the college and surgeon in ordinary to the King.

Brigade-Surg.-Lieut.-Col. David D. Cunningham, C.I.E., I.M.S. (retired), has been appointed Honorary Physician to the King, vice Surgeon-General Sir J. Fayrer, Bart., K.C.S.I., deceased.

Dr. E. M. Grace, the cricketer and coroner, has resigned his position as District Medical Officer and Medical Officer to the Workhouse of Thornbury, Gloucestershire, after forty years' service.

We understand that Dr. William Carter, Senior Physician, and Mr. William Alexander, Senior Surgeon, propose shortly to retire from the active staff of the Royal Southern Hospital, Liverpool.

A marble bust of Dr. Huglings Jackson has been presented to the National Hospital for the Paralysed and Epileptic, Queen's Square, W.C., in recognition of his distinguished services to neurology.

Surg.-Gen. Sir Alfred Keogh, Director-General, gave a dinner at the Royal Army Medical College, Millbank, on the 27th ult., to which guests representative of the War Office and the General Medical Council were invited.

A CLINICAL LECTURE

ON

"OTOSCLEROSIS." (a)

By MACLEOD YEARSLEY, F.R.C.S.,

Senior Surgeon to the Royal Ear Hospital.

GENTLEMEN,—The condition to which the name, "otosclerosis," has been applied is one of which the morbid anatomy has been worked out only comparatively recently, and there is still much to be learned as to its real significance, and, still more, as to the best means of combating its insidious onset.

The term "otosclerosis" is a misleading one, both from the point of view of the morbid anatomy and from the fact that it has led to some confusion between it and the post-catarrhal changes which form the latest stages of catarrhal inflammation of the middle ear. Strictly speaking, it is not a middle ear process at all, but is essentially an affection of the labyrinthine capsule. It is characterised by a bony ankylosis of the stapes in the fenestra ovalis, together with osteophytic outgrowths in the lower parts of the scalæ tympani and vestibule, and in the fossula ovalis, and often with isolated spots of osteoporosis in the bony labyrinthine wall. The membrana tympani is normal, or approximately so, and the Eustachian tubes retain their patency.

The most important changes demonstrable are in the stapes, annular ligament, and those parts of the labyrinthine capsule which are in the vicinity of the fossula ovalis. It appears that the superior and anterior circumference of the oval window is to be regarded as the seat of election of these changes.

The change which takes place in the capsule is a process of resorption of old, and apposition of new, metamorphosed tissue. Macroscopical examination reveals the stapes fixed to the oval window by bone, either along the margin of the footplate, or by means of bony trabeculæ from the stapedial crura to the walls of the fossula ovalis. In some cases the whole margin of the footplate is so fixed by bone that no trace of a joint remains. In many cases the fossula ovalis becomes more or less filled with spongy osteophytic outgrowths. Occasionally osteophytes encroach upon the interior of the labyrinth, and sometimes affect the fenestra rotunda also.

Coincident with these changes in the region of the stapes there may appear foci of osteoporosis in other parts of the capsule, notably in the region of the cochlea, in the modiolus and semi-circular canals. These foci spread towards the endosteum of the capsule, so that the intra-labyrinthine fluid may be separated from the large lymph spaces of the newly-formed spongioid areas only by a delicate membranous partition.

The exact process of this formation of the normal compact labyrinthine capsule into abnormal osteoid new growth has been carefully investigated by Siebenmann and Habermann. The necessary limit of time will not allow me to take you through all its stages in a lecture like this. Suffice it to say that the process begins in the Haversian canals, which become widened towards the side of the labyrinth by lacunar resorption of their walls. At some points this resorptive process proceeds further, whilst at others it results in the apposition of new bone.

Another and important point is that the capsule is peculiarly rich in remnants of primary cartilage, and these become disintegrated and replaced by new bony growth, as do also the cartilaginous coverings of the fenestra ovalis and stapedial footplate.

In the early stages of the condition there is a very sharp distinction between the newly-formed spongioid bone and the surrounding dense normal bone; this is in marked contrast to the absence of any line of demarcation between the spongioid tissue and the sclerosed bone formed in the later stages.

Nearly every investigator has endeavoured to find a cause for the condition I have briefly described. I will not detain you with all the pathengenetic theories that have been enunciated, but will give you the most important only. Numerous earlier theorists have ascribed to otosclerosis an inflammatory origin, but the rarity of any evidence of past or present tympanic inflammation, and the complete absence of signs of inflammation of bone, are strongly against this view.

One of the most probable explanations yet suggested is that of Siebenmann, who considers it to be the final stage of a developmental process which does not normally take place in the petrous bone, but which is the rule in other bones. As I have pointed out, the bony capsule of the labyrinth is rich in remnants of primary cartilage; these are found most frequently about the region of the fossula ovalis, which is the seat of election of the changes just described. In the long and flat bones growth, without change of shape, is brought about by a process of resorption and apposition after birth. The labyrinthine capsule, however, attains its ultimate size at birth, and the cartilage remnants it contains are not, therefore, used up; so that, unless the abnormal development which Siebenmann considers as constituting otosclerosis takes place, they are retained in the capsule until old age.

Gray rejects this theory as in no way explaining the involvement of the stapedio-vestibular articular cartilage. He points out that otosclerosis is rare before puberty, almost uniformly bilateral, more common in women, hereditary, and that certain bodily conditions are recognised as favouring its development (such as anæmia, pregnancy, gout, etc.). Reviewing these facts, together with the peculiar features of its morbid anatomy and the absence of any signs of inflammation, Gray suggests that the sharp line of demarcation between the areas of absorption and the healthy bone means death of the tissue in that area, and that the dead tissue is absorbed without the occurrence of infection. This view is the most satisfactory one at present advanced, and it is pleasing to know that it has been enunciated by a British otologist.

Having thus briefly reviewed the nature of otosclerosis, I must now pass on to certain points in its etiology before dealing with symptoms and treatment.

Otosclerosis is essentially a disease of young people. It rarely commences before the twentieth year, although its occurrence before that period is not unknown. It is far more frequent in women than in men, and the statistics of various observers range from 61 to 50 per cent.; taking my own cases, I find that women are in a majority of 5 to 1. Some explanation for this great preponderance of women lies in the relative frequency of anæmia and chlorosis in that sex, and to the anomalies of nutrition peculiar to the puerperium. It is not uncommon for otosclerosis to date from the occurrence of pregnancy.

A prominent feature in the condition is its hereditary nature. Denker, out of 306 instances, obtained a history of heredity in 40.5 per cent. So far as can be gathered, transmission would appear to have a tendency to take place through the female branches, and it is a known fact that harmful embryonal influences are more likely to affect the female than the male. This fact of heredity, which can hardly be doubted, supports Siebenmann's contention that otosclerosis is an abnormal post-embryonal development rather than a true disease, for, according to the laws of biological heredity, it is supposed that diseases cannot be inherited.

(a) A Post-Graduate Lecture delivered at the Royal Ear Hospital.

A number of agents have been suggested as *exciting causes* of otosclerosis, chief among them being gout, rheumatism, syphilis, anæmia, pregnancy, and the puerperal state, and severe chill. I need do no more than mention most of these, but syphilis and pregnancy require more than a passing notice. Habermann and Gradenigo have been the strongest advocates of syphilis, both congenital and acquired, as an essential agent in otosclerosis, but, so far as I know, there is no real supporting evidence. The aural manifestations of syphilis are definite and well-known, whereas in otosclerosis one sees no other evidences of the disease, nor is specific treatment of any avail.

Pregnancy and parturition are not infrequently assigned by patients as a definite cause of otosclerosis, and the puerperal condition almost always results in a decided increase in the deafness. This adverse influence is probably due to the blood condition, which may favour stagnation in the capillaries, and so bring about the local bone death suggested by Gray as the starting-point of the malady. The same remark applies to gout, rheumatism and anæmia.

Coming now to *symptomatology*, the chief manifestations of otosclerosis may be enumerated as deafness, tinnitus, vertigo and paracusis Willisii (or hearing better in a noise), together with several subsidiary symptoms.

The characteristics of the *deafness* are its markedly insidious onset and progressive nature. It is always bilateral, although one ear may be affected long before the other, even years. In the majority of cases the hearing is affected very gradually, so that patients can make no definite statement as to when the trouble first began. Sudden onset, although it may occur, is distinctly rare. The progress of the deafness is usually slow, and the condition may remain stationary for a variable, sometimes a long period. Again, a more or less rapid and marked accentuation may occur, the patient never recovering the ground thus lost.

Although I shall again refer to the deafness when I speak of the results of functional testing, I may mention here that, in pure ankylosis of the stapes, even in the later stages, the whisper can still be heard in the majority of cases, if only close to the ear, and spoken speech can always be heard. Where the perception of loud speech is lost, pure stapes ankylosis is no longer present, but there is superadded some advanced change in the structural characters of the labyrinthine capsule, or in the terminal nerve apparatus, or the fenestra rotunda is also involved.

Subjective *tinnitus* is a frequent symptom in otosclerosis, and often precedes the deafness. In character it may be buzzing, hissing, singing, humming, roaring, rattling, or pulsating. Though usually constant, it may, in some cases, be intermittent, and is occasionally so intense as to drive the patient to desperation. In one case of Denker's it led to suicide. It is often found that, when tinnitus is only occasionally present in the early stages of otosclerosis, it becomes constant later, and it does not invariably disappear when the patient becomes completely deaf.

Vertigo is not very common, and, when present, is usually slight in character.

The peculiar symptom of hearing better in a noise, or *paracusis Willisii*, is a remarkably constant and early symptom in otosclerosis. I need not enter into the various theories which have been advanced to explain this symptom, but I would impress upon you how frequently and early it occurs in otosclerosis; in one lady under my care it was noted within six months of the onset of the deafness. By most otologists it is considered to be a most unfavourable symptom, although Burkner believes that it is never present in cases which are complicated with affection of the sound perceiving apparatus, and therefore gives a comparatively favourable outlook.

Pain, slight and deep in the ear, and a feeling of tension in the ear, are sometimes complained of. Increase of deafness on straining to listen, due to the inability of the intra-tympanic muscles—put into vigorous action by listening—to put the fixed ossicles in motion, is not infrequent.

On examination the tympanic membrane is usually normal, or nearly so. The chief peculiarity to be noted is a reddish reflex over the promontory or in the area of the stapes This is, however, by no means present in every case. It is due to hyperæmia of the mucous membrane over the promontory or about the fossula ovalis shining through the membrane. This reflex, when over the promontory, is an unfavourable sign, as it points to the extension of the bony pathological process to the labyrinthine capsule.

The Eustachian tubes are patent, inflation giving a large, full sound, and being unaccompanied by improvement in either hearing or tinnitus.

It must, however, be remembered that otosclerosis may be complicated with chronic middle ear catarrh, which may alter the normal condition of the tympanic membrane, middle ear, and Eustachian tube.

In uncomplicated otosclerosis the upper air passages do not usually present any condition especially noteworthy.

Functional testing reveals the presence of what is known as "Bezold's triad of symptoms," viz.:—(1) increase of bone conduction; (2) a markedly negative Rinné; and (3) loss of low tones.

Increased bone conduction is found in uncomplicated stapes fixation, but when, later, the bony labyrinthine wall is the seat of foci of spongioid bone, the bone conduction becomes diminished. All cases presenting Bezold's triad of symptoms in association with normal, or nearly normal, tympanic membranes, and patent Eustachian tubes that have been subjected to post-mortem examination, have been found to have stapes ankylosis. When, however, the disease has so progressed that the changes in the stapedio-vestibular symphysis no longer preponderate, and foci of spongioid change have become marked in the cochlear capsule, the two conditions are opposed. The stapes fixation increases the bone conduction and renders the Rinné reaction markedly negative, whilst the marked spongioid processes in the labyrinthine wall diminsh the bone conduction and decrease the negative Rinné. Owing, however, to the fact that the region of the stapedio-vestibular symphysis is the seat of election of the condition, stapes fixation usually predominates. In rare cases—*i.e.*, in very early stages of otosclerosis—the result of functional testing will be normal bone conduction, reduced air conduction and positive Rinné. In such cases the acoumeter is diminished in proportion to the loss of air conduction, spoken speech is heard relatively well, and the whisper is reduced.

As the disease progresses, bone conduction may be found normal, air conduction absent, and Rinné negative, such cases standing midway between the increased and diminished bone conduction stages of the condition. The greater proportion, however, yield the result—bone conduction increased, air conduction reduced, and Rinné negative. Here the greater the increase of bone conduction the greater proportionately will be the loss of air conduction; acoumeter and voice will be diminished, whisper almost lost, and the lower tone limit will be reduced by one or more octaves.

When the spongioid changes have progressed to a stage when diminution of bone conduction preponderates, both that and air conduction will be found reduced, associated with a Rinné negative. Material reduction of bone conduction may need a differential diagnosis to be made from nerve deafness. This can be done by considering the loss of the lower tone limit, the comparative retention of high tones (as ascertained by the Edelmann Gatton-pfeife), the increasing duration of air conduction as the number of vibrations increases, and Gelle's test.

The last-named test is, I think, certainly useful, in spite of the adverse criticisms to which it has been subjected. Its chief objection lies in its difficulty of application. As a control test to Rinné's reaction, it possesses most value. Without further discussion, I may formulate the following results and their significance:—

(1) If Rinné is negative high up in the scale (to C), Gelle is also negative, and deafness is due to stapes fixation.

(2) If Rinné is negative below or up to C, and positive for higher octaves (C_2), the result of Gelle's test

indicates whether stapes fixation is to be assumed or not.

I have dwelt upon the results of functional testing somewhat at length because I believe them to be important, not merely from the diagnostic point of view, but as indications for treatment. The small attention that has been paid to tuning-fork tests by the majority of British aurists is the chief blot upon British otology.

The *course* of the majority of cases of otosclerosis is slow, but occasionally one meets with instances in which a quickly progressive diminution in hearing, with increasing tinnitus, leads to almost complete deafness within a few months. In the ordinary slow progress, exacerbations may occur, due usually to pregnancy, excessive body chill, anxiety and the like.

From what I have said you will gather that *prognosis* is the reverse of favourable. We are at present quite unable to cure the condition. In a few cases relief from the tinnitus can be afforded, or the otosclerosis even brought to a standstill. Those cases in which the reddish promontorial reflex, already alluded to, is present usually progress rapidly and ultimately reach a high degree of deafness.

Treatment does not promise much. I am not going to discuss the numerous operations—radical mastoid, removal of the stapes, or formation of a new opening in the bony labyrinthine wall—that have been suggested and practised with varying results, mostly the reverse of encouraging.

Prophylaxis, in regard to the evil effects of pregnancy and chill, should certainly be kept well in mind. Conception in otosclerotic patients should be avoided, and female descendants of otosclerotic persons should be advised not to marry.

When otosclerosis is present, numerous drugs have been suggested for its treatment. Iodide of potassium, in daily doses of about 15 gr. in half a pint of water immediately after food; antipyrin and salicylic acid in small doses; arsenic, iron, bromides, strychnine, thyroid extract—all have been recommended and found wanting. The drug which has received most universal attention is phosphorus, which, according to Mirwa and Stötzner, retards the formation of normal spongioid bone in the long hollow bones. It may be given in oily solution or in glutoid or keratin capsules, and is best administered in small doses given for a long period of time. Caution is necessary, as it may cause digestive disturbances.

As regards local measures, nearly all those hitherto employed have been with the object of mobilising the stapes. They resolve themselves into two groups—intra-tympanic injections and passive movements. Inflation with air alone (by catheter or Politzer douche) is useless, and may do positive harm. In place of air, steam, nascent chloride of ammonium, vaseline, pilocarpine, and solutions of pepsin have been suggested. More recently the use of a fluid ointment containing red oxide of mercury injected through the catheter and combined with rapid otomassage has been advocated.

The best results hitherto recorded seem to have accrued from the judicious application of otomassage, and I am inclined to believe that any successful treatment of otosclerosis will be obtained by this means.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Dr. Chantemesse, Professeur Agrégé of the Faculty of Medicine of Paris. Subject: "The Serum Treatment of Typhoid Fever (Antityphoid Opsonisation)"*

ON December 4th, Elisa Dehring, 50, a cook, lately in service at Crediton Road, West Hampstead, was before Mr. Paul Taylor charged with being accessory to the murder of a married woman, 28 years of age, who died in St. Mary's Hospital on August 9th last, as the result of an illegal operation. Mr. Symmons prosecuted for the Treasury. Mr. Paul Taylor committed the prisoner for trial at the Central Criminal Court, not, however, on the original charge, but, at the request of Mr. Symmons, for various other alleged offences in connection with the woman's death.

ORIGINAL PAPERS.

THE COLOUR OF THE MUCOUS MEMBRANES AS A GUIDE TO THE CONDITION OF THE BLOOD, AND AN INDEX OF THE NUTRITION OF THE BODY.

BY ALEXANDER HAIG, M.A., D.M., OXON., F.R.C.P., LOND.,

Physician to the Metropolitan Hospital and to the Royal Waterloo Hospital for Diseases of Children and Women.

SOME years ago I produced a card of graduated colours corresponding with those of the mucous membranes, the palest colour being that usually met with in chlorosis or anæmia, and the darkest being that met with in those who maintain a good standard of health and nutrition on a uric-acid-free diet (*a*). The other colours are intermediate between these extremes, and to make the card more useful I placed under each colour the numerical index of the corresponding blood decimal—*i.e.*, the decimal per cent. hæmoglobin divided by per cent. red cells. Now in chlorosis the common decimal is about .5 or less, and that of the deepest colour is more than a whole number—*i.e.*, 1.1.

We thus get four colours for comparison with the mucous membranes, and the numbers corresponding are .5, .7, .9, and 1.1, and in examining a case we can enter it in our notes as any one of these, or, if it is intermediate, then as .6, .8, or 1.0 (*b*).

I propose now to mention some of my results with this card, to describe the best methods of using it, and the extent to which it may be relied upon as an index of blood condition and general nutrition.

It does not, of course, pretend to be more than an approximate guide to the actual blood decimals, and whenever the pale colours indicate distinct diseased conditions, examinations of the blood itself should always be made to supplement the information given by the card, and also for the purpose of examining the numbers of the various kinds of cells and their forms.

The whole object of the card is not to do away with the necessity for blood examination, but to tell us, as it does in two minutes, whether there is, on the one hand, anything far wrong with the vital fluid calling for further investigation, or, on the other, whether a patient, whose blood decimal had been recorded six or twelve months before, was keeping up a condition of good and satisfactory nutrition, or whether that nutrition was improving or falling off.

The mucous membranes that are generally made use of for the purpose of obtaining the approximate blood decimal are those of the mouth and eyes.

It is well to have the patient seated on a chair, and facing a good light, but not in direct sunlight, which is apt to cause dazzling reflections. I may say that the cards are not intended for use by artificial light, and that if they are so used they will probably give results that are from 10 to 15 per cent. too high.

A fairly good idea of the index may be obtained simply by watching the patient smile; the only objection is that as the lips are drawn up, there is apt to be some pressure on the gums, squeezing the blood out of them so that the index may be too low.

The best way to examine the gums is to take the lower lip and pull it gently down so as to expose the lower gums without exerting any pressure upon them.

Having done this, place the colour card just below them and slide it along to right or left till the nearest tint to that of the gums is vertically below them.

It must not be expected that the colours will tone absolutely in all cases. It is practically impossible to produce artificially the exact tint of the blood as seen in the mucous membranes, but you should obtain as nearly as possible the tint or depth of colour visible in the gums, and if it is intermediate between two colours, mark it with an intermediate number.

In order that the result obtainable from the gums

(*a*) Copies of this card can be obtained from Messrs. Bale and Danielsson, London. Price 1s.

(*b*) Note the numbers on the cards at present obtainable have, for reasons which I explain in a forthcoming new edition of "Uric Acid," been marked too low and should be altered as above for comparison with ordinary standards of blood examination.

may be moderately reliable, there must be no irritation of any part of the gums from dental periostitis or the accumulation of tartar. Therefore, look at the general tint of the whole gum surface, not at one spot.

But since the colour of the gums may be misleading from some of these causes, it is always well to use other mucous surfaces for comparison, and to enter the result of such comparison rather than the colour of any one.

The colour of the lips, as seen in their natural position, is always too dark from the presence of pigment, but the tint of the inner surface of the everted lip may be used if this eversion can be managed without squeezing the blood out of it.

Again, if the tongue is clean, and it is protruded in such a manner as to force the blood moderately into the surface of its mucous membrane, this may give a fairly reliable index.

As to the eye, the blood decimal may be read from the lower lid simply by pulling it downwards (though this is very often congested, and yields too dark a colour), or, better, while gently fixing the lower lid, make the patient look outwards, so as to expose the mucous membrane covering the caruncle at the inner canthus, and take the general tint of the surface thus exposed.

In all cases it is the general tint or the average tint of all these exposed mucous surfaces, rather than the tint of any one of them, that is to be used in arriving at the approximate blood decimal.

Now as to the use of this blood decimal when obtained. It has long been my habit to note this in all patients when they first come to me, and at each subsequent visit, and the observation is so easily and quickly made that it soon becomes a routine.

I thus get most valuable information as to the condition of the blood and general nutrition, and am able to see at a glance whether a patient is improving, standing still, or going back, as time goes on.

As a rule, middle-aged people living on an ordinary mixed diet do not show a blood decimal above .7, or at most .8, and, of course, those who come to a doctor are not in the best of health, or they would not come.

But those who live on a mixed diet never have quite such a high blood decimal as those who live on the uric-acid-free diet, and while 1.0 and 1.1 are reached by those who do well on this diet, and have been on it for about three or four years, and especially by children and young people whose nutritive processes are active, there are practically no meat-eaters who attain to 1.0, just as there are no meat-eaters who have as quick a capillary circulation as those who swallow no unnecessary uric acid.

Those who attempt to get on to the uric-acid-free diet, but fail from one cause or another to take sufficient albumen, not only do not show an improving blood decimal, but often present to us a great and decided falling-off below even the level of the ordinary meat-eater, because to alter diet without taking sufficient nourishment is to have low acidity of urine and high alkalinity of blood; hence the blood is flooded with uric acid from the old stores, and the blood decimal rapidly deteriorates.

Such people have depression one day and rheumatism the next, as the uric acid excess oscillates back and forward from the blood to the fibrous tissues, and from the fibrous tissues to the blood, and it is the latter change that markedly brings down the blood decimal.

This is well seen in the case of chlorosis, especially if the chlorosis (as is often the case) has been preceded by rheumatism.

It is the very same uric acid which in the girl of 13 causes rheumatism, and in the same person at 17 causes chlorosis, and between these two ages there is a more or less constant alternation of excess of uric acid in the blood, with increasing anæmia, and excess of uric acid in the joints and fibrous tissues, with increasing rheumatism.

And the blood decimal will at once tell us which way the pendulum swings, for with rheumatism at 13 there is a much higher decimal (at first almost normal—say, .9 to 1.0), and with chlorosis at 17 there is a much lower decimal tending to get even lower still if the case is untreated.

When I see a case of chlorosis with a decimal of .5 or less, I never put that on to a uric-acid-free diet, as to do so would aid the solution of uric acid in the blood and make matters worse.

Here we must first cure the patient with iron and any food she can best take to make sure of sufficient albumen (without which neither good blood nor any other tissue can be made), and when the decimal has got to .7 or .9, then slowly alter the diet, taking great care that the proper quantity of albumen is not on any account allowed to be missed.

For similar reasons the gouty old squire type of patient (who leads a healthy out-door life and is troubled by nothing except occasional gout in his big toe) is the one who shows, as a rule, the best decimal for the meat-eaters, and may even get up to .9. For he, like the rheumatic girl of 13, is exactly the person who has most uric acid in his joints and fibrous tissues, and least in his blood.

And this is a favourable condition for the blood, which shows a relatively high decimal.

But when this man breaks down from advancing years, or breaks his leg in a motor smash, or is otherwise laid up, there comes his bad time, and all the uric acid stored in his tissues in previous years begins to pass into his blood, and his decimal falls to .7, .6, or even lower, according to the amount of uric acid passing through the circulation, and the length of time it continues to be present in the blood in excess.

The blood decimal of the ordinary mixed feeder is about .6 or .7, and if he alters his diet you must be content if it does not fall off in the first six or nine months.

By the end of twelve months it may have begun to improve slightly; in the second twelve months there should be more decided improvement, and by thirty or thirty-six months it should be .9 or 1.0 if nutrition is being properly kept up (*i.e.*, if sufficient albumen is being taken).

And this is where the great value of the colour card shows itself. It would be absurd to examine a patient's blood at every visit. If it has been examined at the first visit and found normal except for deficiency of colour, and if colour has been improving on the reformed diet, it is unnecessary to examine the blood at each visit, and there are few patients who would care for the trouble involved.

But with the card one can feel confident that one is not overlooking any serious blood disease, and if the decimal is improving one knows with practical certainty that nutrition is satisfactory.

Again, the card is of great use in the treatment of anæmia and chlorosis by iron or other drugs (*e.g.*, iodide of mercury often more powerful than iron—see case and fig. in "Uric Acid," Ed. VI.) which clear the blood of uric acid; and it is because iron clears the blood of uric acid it does good in chlorosis and anæmia. If such troubles as dyspepsia or diarrhœa prevent it acting on the uric acid and clearing it out of the blood, then the blood decimal will not be found to improve under its administration.

But under ordinary conditions the decimal improves so much under the proper administration of one of these drugs that if the card is used, say, once a week, a quite visible improvement can generally be observed and recorded. The improvement (except under iodide of mercury) is often slow at first, but becomes more marked in the third, fourth, and subsequent weeks.

For all these purposes the card is most useful, but it is a good thing to examine the blood also at the first visit, as this ensures that nothing is being overlooked, and also gives us an opportunity of comparing the result with the reading given by the card.

On the other hand, if the colour does not stand still on the new diet, but falls lower and lower, we may infer either that the patient is not doing the diet correctly (*i.e.*, has not left off all the poisons), or that he is not taking sufficient albumen.

For the blood will not improve if nourishment is deficient (nothing can be made out of nothing), and this is so even if drugs are being used. The blood decimal will not improve on iron if nourishment is deficient, or if dyspepsia prevents its full and complete utilisation. Dyspepsia may also hinder recovery by preventing the absorption of the iron.

If we follow these facts carefully it soon becomes evident that the cause of anæmia is the presence of excess of uric acid in the blood; and that its cure by drugs (iron, mercury, copper, etc., all of which form insoluble compounds with uric acid) is the clearing of such excess out of the blood, though the cure is often temporary enough, as the urate is only driven into the fibrous tissues (where it may cause various amounts of pain as evidence of its whereabouts), from which it is practically certain to return into the blood at some future time when the retentive effect of the metals has passed off; and that its prevention is the keeping of the body moderately free from any large quantities by means of the uric-acid-free diet.

All this and much more, which I have no time to mention, is rendered sufficiently obvious by the steady routine use of the blood decimal card.

A little practice soon gives all reasonable accuracy as to the results recorded, and the card is a boon to the busy practitioner, who can carry in his waistcoat pocket a means of testing in a moment the blood condition of numbers of patients, when lack of time would quite prevent him from drawing a sample of blood and estimating both cells and hæmoglobin with instruments. But he can always fall back on his instruments when the colour card reveals the presence of very abnormal conditions.

I say again the card gives only the approximate blood decimal, but its constant use reveals many interesting facts as to the causation and concomitants of anæmia and chlorosis, and their relation to uric acid and rheumatism, and the effects of treatment by drugs or diet in prevention or cure.

DIPHTHERIA AND SCHOOLS. (a)

By JAMES NIVEN, M.A., M.B.,

Medical Officer of Health, Manchester.

THE subject may conveniently be divided into two parts, the first concerning itself with the question whether elementary schools have caused an increase in the prevalence of diphtheria and the manner in which it spreads in schools; the second, with the mode in which the spread of diphtheria in schools may be combated, and the relation of such action to the prevention of diphtheria generally.

It does not follow because diphtheria spreads in elementary schools that the incidence of the disease must be increased by increased attendance at school. This problem has for a long series of years been studied by Sir Shirley Murphy, in a manner calculated to give an answer to the question raised. From a comparison of the death-rate from diphtheria and membranous croup at school ages, and at younger as well as more advanced ages, in the decade preceding the Elementary Education Act, 1870, which made attendance at school compulsory, with the death-rate from these conditions at the same age groups in the decades following and in the quinquennial period 1901-05, he shows that the diminution of the death-rate at school ages has been less than that occurring at other ages, or the increase has been greater at that period of life.

The incidence of diphtheria has, in fact, been shifted so as to fall more than formerly on children at school ages. Nor can this conclusion be said to be invalidated by the greater precision which has been attained in respect of diagnosis in recent periods, as Sir Shirley shows.

Granted, however, that so much has been clearly made out, it does not necessarily follow that a greater total incidence of diphtheria has thereby been produced, since, unless it can be shown that school life has a special tendency to produce outbursts of diphtheria such as would not occur in the ordinary course of life of children not attending school, all that has occurred may have been merely a shifting of incidence and not an increase of the total number of cases. It might be supposed, for example, that, if school children remained at home, and were infected, as a number of them no doubt would be, the younger ones being more in contact with those still younger than themselves would infect them to a greater extent than before, and the older ones being, perhaps, at work would increase the amount of diphtheria amongst their seniors. Nor are there wanting occasions on which the closure of schools has seemed to produce such a result.

Sir Shirley Murphy has been led to consider the effect of school holidays on the incidence of diphtheria, and he has shown that the autumn holiday produces a decided diminution in the reported number of cases, both of diphtheria and of scarlet fever, amongst children at school ages, a diminution which is not necessarily experienced either at younger ages or amongst older persons. Here, again, there can be no doubt that the effect of school attendance in summer is arrested by the advent of holidays, but it is not certain that the improvement at school ages is entirely real, or that, even if it were, the effect of the holidays at that season is not a more important factor than the interruption of school life.

It will be seen that, even after Sir Shirley's refined and elaborate analysis, the question of the effect of school life on the spread of diphtheria in the community admits of further study. I have, therefore, referred first to the careful investigations made by the staff of the Local Government Board into particular outbreaks of diphtheria, in the period preceding the discovery of the diphtheria bacillus, and in the subsequent period before it had come to be considered a necessary part both of investigation and administration, as well as to Sir Richard Thorne's work, which summarises these and other reports.

From these sources we learn that the manner in which outbreaks of diphtheria are preceded and accompanied by slight sore throats, plainly of a diphtheritic nature, was clearly made out. The part played by other infectious diseases, and particularly by scarlet fever, in causing diphtheria was emphasised. The infective power of special cases, and the persistence of infective power in particular cases, were recognised. The effect of rhinitis in causing infection was not, and could not be, so clearly defined, as it has subsequently become. But the influence of the school was in some instances sharply defined, and it was shown by Mr. Power, in one outbreak, that the children at school were living in an infected atmosphere, similar to that existing in households invaded by diphtheria. Mr. Power also emphasised the manner in which diphtheria introduced, on more than one occasion, into the village school, by cases with slight or without clinical symptoms, appeared to gather intensity as one child after another was attacked. On another occasion, school children apparently became affected in the course of scrambling play along with other infected children, but in a manner independently of school life. On a third occasion where a day-school was severely invaded, the disease spread especially amongst the children living in a particular part of the district.

It appears evident that the aggregation of children in elementary schools must have the effect of diffusing diphtheria in a number of instances sufficient when taken together to affect the total incidence of the disease, and that the power of the schools to affect the total incidence of diphtheria will be greatest in sparsely-populated rural districts.

It has appeared to me that it would be advantageous to study more closely the behaviour of diphtheria in relation to schools in the city of Manchester, a study for which I possess a number of apposite facts.

Premising that the cases may, with few exceptions, be regarded as diphtheria, owing to the careful bacteriological and clinical sifting to which they have been subjected, I give the facts as follows.

As regards the number of cases accepted finally as diphtheria in individual years from 1897 to 1906, and the aggregate numbers accepted, at each year of life up to ten, in the aggregate a great increase is shown in the number of cases at age three, which is the year of maximum incidence. A small decline takes place at ages four and five, and a marked drop at age six. Now, in Manchester, the numbers attending school at age three are not much over one-third of the numbers attending at age four, and the numbers attending at age four do not greatly exceed one-half of the numbers attending at age five.

(a) **Abstract of Paper read before the Second International Congress on School Hygiene, London, 1907.**

Hence the year of maximum incidence precedes the years of school life. It is, however, the year in which children will first be brought into intimate intercourse with each other and with school children in the course of play out-of-doors. I have already mentioned one instance in which the scramble of play appeared to have a special influence in the diffusion of diphtheria.

A study of the facts for individual years appears to show that as the wave of diphtheria rises the number of cases increases most markedly at school ages and at younger ages, the increase in adults following later. Further, as the wave rises year by year there is a tendency for the age of maximum incidence to advance to the fourth year, and in exceptional cases to the fifth. In every year there is a marked drop in the number of cases in the sixth year of life. The influence of school is thus a special one, and is most marked when the total incidence of diphtheria is greatest—that is to say, when more opportunities are given for its manifestation. This is a result which Sir Shirley Murphy had also arrived at by his method of examining the subject. The great drop at age six is probably due to the widespread establishment of immunity.

Next, there is the number of cases for ten years of diphtheria occurring in the separate elementary schools of Manchester, quarter by quarter. That the significance of this statement may be understood, it is necessary to premise that the number of public elementary schools in 1906 was 177, and the number of children on the books 109,765, the average attendance being about 90 per cent. It will be seen that diphtheria affects particular schools in two forms, either as special outbursts or in the form of a low and steady persistence.

The latter form is greatly influenced by the number of scholars and by the amount of the disease present in the district. The outbreaks or flare-ups, however, which take place in particular schools are more or less independent of these circumstances and constitute the true school influence. They are due, no doubt, to the aggregation of susceptible children in the infant departments of the schools affected, subjected to some particular cause of a temporary character.

It is probable that this cause is the presence of some child or children possessing the power to produce copious discharges, rich in diphtheria bacilli, while themselves not suffering. Many such cases have been found, particularly among cases of diphtheritic rhinitis, whether post scarlatina or otherwise, but the tonsils also are affected in a similar manner.

The tendency of such flare-ups to last only a limited period, and to burn themselves out, provided no more children are meantime introduced into the class, is a noteworthy circumstance.

It cannot be doubted that such flare-ups, which are a special product of the aggregation of susceptible material, do add to the diffusion of diphtheria in the community. The degree to which they do so is to be measured by the number of such flare-ups and the number of cases occurring in course of them. Yet it is not to be forgotten that similar occurrences would, though less frequently, take place independently of elementary schools.

Another interesting mode of considering the question is the comparison of the death-rate from diphtheria in the three main divisions of Manchester at ages 0—3, 4—14, and above 15. It will be seen that while the death-rates at ages 0—3 and above 15 do not differ widely in the three divisions of the city, the death-rate in North Manchester is between two and three times as great, at school ages, as the corresponding death-rate for the Manchester township. This is the more remarkable inasmuch as the Manchester township is the poorest portion of the city, and, on the whole, possesses the poorest schools. It might be inferred that school diphtheria pursues a course of its own, independent of that followed by diphtheria at other ages. As we have seen, this is true only partially, and the figures require explanation. It is, however, partially true.

This comparison leads us to observe that the sanitary condition of the schools appears to have, upon the whole, little to do with the occurrence of these outbreaks, which are, in a measure, fortuitous, and dependent apparently on the aggregation of children not yet immunised, and on their opportunities for infecting each other. It has been suggested to me by my assistant, Dr. Goldsmith, that the absence of playgrounds in the centre of the city may be the essential fact, a suggestion which chimes in with the conclusion to which I had already come that the scramble of play was probably the most important fact in the diffusion of diphtheria. Nevertheless, crowding together in the schoolroom and the use of common articles must also contribute.

I have also analysed the cases of diphtheria occurring in a particular year—an analysis which, while establishing some degree of exchange of infection between school and younger children, again appears to show that diphtheria in school children is largely spread in school, and diphtheria in persons outside school is largely spread independent of school.

It is, however, very difficult to arrive at a secure position. It is manifest that diphtheria is one of those diseases in which the slight or latent cases far outnumber the discoverable cases. This is probably true also of enteric fever, pneumonia, and cerebro-spinal fever.

All these different lines of investigation, then, go to show that diphtheria finds in the earlier period of school life a favourable occasion to extend itself, and that, in fact, it is in this manner widely diffused.

Some facts given by Dr. Graham Smith in his excellent paper in the *Journal of Hygiene*, Vol. II., go to show that about one-half of school children and a much higher proportion of adults may have harboured diphtheria on a membrane sufficiently invaded to have allowed the system to absorb toxin in small quantities, and so to elaborate a protective anti-toxin. Moreover, when diphtheria has definitely invaded a school, the proportion of harbourers is always high.

Further, Dr. Graham Smith shows that the proportion of persons in the poorer districts of an urban community harbouring the Hofmann bacillus is generally high, and I would suggest that in this circumstance may be found the explanation of the comparatively low incidence of diphtheria on the poorer districts. It is not suggested that there is not a pseudo-diphtheritic bacillus, but that the "short" or "suspicious" bacillus is frequently a true diphtheria bacillus, and in all probability the so-called Hofmann bacillus has frequently been a diphtheria bacillus. I understand from Professor Delepine that he recognises the short form of the diphtheria bacillus by its rapidity of growth on Loeffler's serum, by its cultural characters, by the arrangement of the bacilli in cultures, and by the development of involution forms. There appears to be a considerable margin of doubtful forms, which may be capable of slowly producing immunity. No doubt Professor Cobbett's work is valuable, in giving more precision to the observation of morphological differences. At the same time, the facts seem to point to a widespread production of immunity, especially in the poorest districts, through bacilli of comparatively low virulence. It would be highly interesting to know whether a similar difference exists in different parts of other large towns.

How, now, are we to deal with the occurrence of diphtheria in school? It appears impossible, usefully, to separate this question from the allied one, how we are to deal with diphtheria generally. It is now admitted that all cases of suspected diphtheria should be examined bacteriologically, and it may be added that swabs should be taken from both throat and nose. It is further generally admitted that, while bacteriological confirmation should be sought in all cases, medical practitioners should inject antitoxin on the appearance of suspicious signs and symptoms without delaying to ascertain the result of bacteriological examination. Nevertheless, swabs are not and cannot always be carefully taken, and the conditions are not always favourable to the taking of swabs which will yield true results.

Further, unless the public health bacteriological examinations are made by experts, with great experience, there is a decided risk of cases being classified as not diphtheria which should not be so classified. On both accounts, there is a real danger that the establishment of bacteriological examinations may lead to the spread of diphtheria, owing to a false sense of security being produced in respect of infective persons.

No serious case of throat illness, presenting signs of diphtheria, should be entirely rejected simply on bacteriological grounds, although the absence of diphtheria bacilli should cause caution to be exercised in placing such persons in the same ward with clear cases of diphtheria, for the sake of the latter.

The clinical diagnosis, then, still remains as necessary as ever, and bacteriological examination must be regarded as only an aid, especially in the absence of a staff such as the Public Health Authority in New York has provided.

In the circumstances of public health administration holding in this country, it is very desirable that all cases of diphtheria should be removed at the earliest possible moment after the commencement of symptoms. If this cannot be done, a serious responsibility rests on the medical practitioner who omits to administer antitoxin within the first three days of illness.

No further principles of action can be laid down applicable to all authorities, nor does it seem desirable that they should be. If, under any system of administration, there is very little diphtheria in the district, and schools are not invaded, it would be better to continue on existing lines, until a necessity arose for acting otherwise. *Quieta non movere.* If diphtheria is present in the district at a moderately high level, more action is called for. In that case, bearing in mind the necessity of submitting all specimens to a bacteriological expert with large experience, and versed in public health work, swabs should, when possible, be taken by an officer of the sanitary authority from the throat and nose of members of any family who have been exposed to infection, and should be submitted to bacteriological examination.

Cases harbouring diphtheria bacilli should receive a prophylactic dose of antitoxin, and may usefully be removed to an isolation hospital to be kept under observation until free from bacilli on three negative swabs. No child attending school from such a family should be allowed to return to school while harbouring bacilli. Breadwinners may be allowed more latitude. But even breadwinners should not go to work while harbouring bacilli, without being required to use precautions in the way of antiseptic gargles, and nasal douching of a gentle character with antiseptics.

Cases isolated in hospital are, usually, not discharged except after three negative swabs have been taken. But Dr. Newsholme's practice appears to be a good one—viz., to exclude diphtheria convalescents from school for six weeks after discharge from school and recovery at home. Apart from the question of infection, such children are often weak, and susceptible to other forms of disease—a consideration which might well be taken into account by school authorities in connection with other forms of disease. There are considerable difficulties in the way of obtaining three negative swabs from children treated at home, and on this account also Dr. Newsholme's plan appears a good one.

THE ACTION OF CERTAIN SALTS OF FORMIC ACID ON THE CIRCULATORY AND MUSCULAR SYSTEMS. (a)

By ALEXANDER GOODALL, M.D., F.R.C.P.ED., AND ISABEL MITCHELL, B.Sc.

DR. GOODALL first referred to the extensive use which was at present made of formic acid and its salts in therapeutics, and to the very laudatory terms in which they had been advocated, particularly by French writers. He thought that some of the assertions as to the scope of formic acid were extravagant, and noted that Dr. Ker and Dr. Croom, who had written a paper on the use of these remedies in diphtheria, were much more cautious in their statements than Huchard had been. He had thought it, therefore, important to investigate the physiological action of the formates by experiments on animals. In the work he has made use of ordinary physiological methods, and as he had found that formic acid was too irritating to admit of its use, he had employed the salt of sodium, potassium and calcium.

Effect on Blood-pressure.—In the case of all these salts the only action observed was a depressant one; that is, the drug, as soon as it produced any noticeable effect at all, was toxic. Sodium formate had little action of any kind, except in strong solution, and the fall in blood-pressure was usually temporary. Potassium formate was more powerfully depressant, and was fatal in strong solutions. Calcium formate was depressant in dilute solutions; in stronger solutions the blood-pressure was raised again. Formic acid was purely depressant. In the case of sodium, potassium, and calcium, the action of the metallic ion preponderated over that of the formate. The Na-ion was inert; the Ka-ion was depressant; and the Ca-ion raised the blood-pressure. The next series of observations were made on the vessels of the isolated heart, with much the same result; potassium formate was rapidly toxic; sodium formate transiently so, and calcium formate stimulating. Their actions on the vessels were also tested by counting the rate at which drops fell from a divided artery of a frog when the circulation was perfused with solution of formate. All the salts caused a transient vaso-constriction followed by a longer period of vaso-dilatation. Sodium formate caused least vaso-constriction and most vaso-dilatation; potassium formate caused most vaso-constriction and least vaso-dilatation, while calcium formate was intermediate between the two.

The action on skeletal muscle was investigated on ordinary muscle, never preparations. The general effect of the formates was greatly to lengthen the latent interval, and to induce fatigue more quickly. Some experiments on man were also undertaken. In doses of several grammes no subjective sensations whatever were experienced. Tracings were taken by means of the ergograph. Some of the observers practised with the ergograph until a uniform tracing was secured; others took simply a tracing before and after formates. It is well known that in using the ergograph great improvement is manifested in the errors after a little practice. In the case of the two subjects who practised formates seemed to diminish the output of work. In the observer who did not practise the ergograph, tracing after formates was slightly better than that taken before the drug was administered. Records made by the dynamometer showed no improvement after formates. Lantern slides of the various tracings made were shown, and fully confirmed the statements made by Dr. Goodall. The conclusions were that formates were almost useless drugs; in all probability they were rapidly converted into carbonates in the tissues. Sodium formate was practically inert. Calcium formate might find a sphere of usefulness as a readily absorbed and not unpleasant calcium salt, and be given in cases of hæmorrage, such as hæmophilia in which the action of the Ca-ion was desired.

LORD STRATHCONA presided over a special meeting at Saffron Walden, held in aid of the Essex Asylum for Idiots, Colchester. A resolution was unanimously passed that the meeting approved of a special effort being made in the district to raise £5,000 for the purpose of building an isolation hospital near the asylum for the treatment of tuberculosis and other infectious diseases.

(a) Abstract of Paper read before the Edinburgh Medico-Chirurgical Society, December 4th, 1907.

OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

Pott's Fracture.

By Peyton Beale, F.R.C.S.

Amongst the out-patients was a man, æt. about 50, who was complaining of considerable œdema of the right foot, very marked trophic disturbances evidenced by eczema over the region of the lower end of the fibula, wasting of the muscles of the lower part of the leg and foot, with inability to bear weight on the latter. On feeling the fibula it was evident that he had suffered from a Pott's fracture, and from his history it appeared that this had occurred about 18 months ago. He said that his leg had been put up in splints, and he had been admitted to a hospital, where he remained for six or seven weeks. The leg and foot were then put up in plaster, and this was removed about six weeks subsequently. On examination there was a great amount of thickening about the lower three inches of the fibula, including the external malleolus; the patient had a flat foot, with very marked eversion of the foot; the skin over the lower end of the fibula was thin and eczematous, and there was a small ulcer commencing just above the malleolus. Mr. Beale said that this state of affairs was found very commonly after Pott's fracture in oldish people. There were, of course, many varieties of fractures of the lower end of the fibula. The fracture nearly always occurred at the weakest part of the bone at a point about three inches above the tip of the malleolus, the upper end of the lower fragment being displaced inwards; this resulted in an outward displacement or eversion of the foot. The different varieties of the lesion were mainly due to the injuries which took place at the inner malleolus as to whether this was fractured or whether the internal lateral ligament was ruptured to a greater or lesser extent. Accompanying fracture there was commonly considerable effusion of blood, and when the blood clotted and subsequently became organised, it caused blocking of lymphatics and veins, often leading to considerable œdema. He ventured to think the following line of treatment was the best to adopt in order to obtain the best results: for the first two days an evaporating lotion should be applied to the leg and foot, the patient lying in bed with the foot raised; then a Dupuytren's splint should be used. This is applied on the inner side of the leg, its upper end being fixed below the knee; a large pad is inserted between the splint and the leg about three inches above the internal malleolus; the foot is then securely bandaged to the forked lower end of the splint, so as to fix it in a position of marked inversion; the splint should be removed twice daily, and the foot and leg massaged from below upwards. If for any reason there is an objection to the Dupuytren's splint (by its use alone it may sometimes be difficult to counteract backward displacement of the foot), a back splint with a foot piece may be employed. The foot piece should be at right angles to the splint, but should be fixed "on the skew" in such a way that when the sole of the foot is applied to it, it keeps the foot in a position of marked inversion. Such a splint is found to give great comfort to the patient, and most effectually prevents the eversion and flat foot which are found so commonly to occur after Pott's fracture.

As regards this particular case, the only thing to be done now was to carefully strap the foot, inverting it as far as possible, and apply massage to the leg daily; the strapping should be renewed as the œdema diminished. Of course, proper dressings would be applied to the ulcer and eczematous skin before the strapping was put on. The patient would also be given a tonic containing iron, quinine and magn. sulph.

OPERATING THEATRES.

WEST LONDON HOSPITAL

Case Illustrating One of the Complications Following Iliac Colostomy.—Mr. Swinford Edwards operated on a woman, æt. 54, who had been admitted with advanced carcinoma in the upper rectum. A careful examination showed that the disease was fixed to the sacrum, and, as the stenosis was considerable, Mr. Edwards thought that a colostomy should be performed without delay. The patient was somewhat obese, and the abdominal wall was flaccid and pendulous. The operator made the ordinary incision, but on account of the adipose tissue it had to be of greater length than usual. After the various muscular layers of the abdominal wall had been split in the direction of their several fibres, the peritoneum was opened. The colon was easily found, and as the mesentery was sufficiently long, there was also no difficulty in bringing a knuckle well out through the wound. The parietal peritoneum was next sewn with interrupted sutures to the edge of the skin wound. A glass rod was now passed through the mesentery transversely across the wound, resting on the abdominal wall on each side of the incision. In this way the posterior wall of the bowel was on a higher level than the surface of the skin, thereby ensuring, as the operator pointed out, a good spur. The bowel was now fixed to the margin of the wound with several interrupted silk sutures, passing, where possible, through one of the longitudinal bands. Several appendices epiploicæ were ligatured and removed, the ligatures in a good many instances being used afterwards as sutures, thus anchoring the bowel yet further to the abdominal parietes. The bowel was not opened, and after a layer of protective matter had been placed over the operation area, the usual dressings, consisting of gauze and cotton wool, were applied, a many-tailed bandage being put on over all.

The subsequent history of the case was as follows: Mr. Edwards opened the bowel on the third day by slitting it up from end to end—that is to say, in the long axis of the gut. On removing the dressings, the glass rod was found loose in them, having slipped from under the gut. The bowels acted after a lapse of another two days, and all went well until ten days after the operation, when the patient, being troubled with a bad cough, felt something occur under the dressing, after a violent fit of coughing. Thinking that there was an action of the bowel, a nurse was called, and on exposing the wound found that a large knuckle of small intestine had prolapsed by the side of the artificial anus at the upper part of the wound. The house surgeon was communicated with, and, as Mr. Edwards's colleague, Mr. Bidwell, happened to be in the hospital, he was asked to see the case. It appears that the bowel had been prolapsed a sufficient time to allow a coating of lymph to form. The gut having been carefully cleansed, was returned, and four or five deep silkworm gut sutures were passed in through the upper part of the wound, including the walls of the colon, and, in order to afford greater support, they were passed through all its coats, thus effectually preventing any further prolapse. Four days after this second operation, it is satisfactory to record, the patient appeared none the worse for this accident. Mr. Edwards remarked that it is well-known the chief risk in colostomy is prolapse of the abdominal contents. He had never known, however, this accident to occur so late as in this case. In his opinion the following reasons conduced to the *contretemps*: (1) a large pendulous and flabby abdomen; (2) the employment of a glass rod instead of sutures; (3) the union of the parietal peritoneum to the skin; and lastly (4) the occurrence of undue muscular expulsive efforts due to the cough. In this case Mr. Edwards said he used a glass rod in order to get a better spur than even could be got with a deep suture. He sutured the peritoneum to the skin, a method which he largely practised in former days, but which he has since abandoned in the majority of cases. He did this on the present occasion in order to cut off the subcutaneous fat from the wound, hoping thereby to prevent fat necrosis and suppuration, which are of somewhat frequent occurrence after the operation of colostomy in the obese. In any future case where he judged that it was advisable to suture the peritoneum to the skin, he would substitute for the glass rod a deep mesenteric stitch, passing through the mesentery and both lips of the wound. Should this method not appear to sufficiently raise the colon, a glass rod might be used in addition. Practically, he remarked, he always used the deep suture, as by this method the large opening into the abdomen is converted into two small openings. This undoubtedly prevented any prolapse of the abdominal contents, even should no peritoneal sutures be placed into the gut.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE

NEUROLOGICAL SECTION.

MEETING HELD WEDNESDAY, DECEMBER 4TH.

The President, Dr. C. E. **BEEVOR**, in the Chair.

Dr. J. S. **COLLIER** read a paper on

CERTAIN PECULIARITIES OF INTRA-CRANIAL GUMMATA IN RELATION TO THE EFFECT OF ANTI-SYPHILITIC TREATMENT.

He first gave an account of the case of a middle-aged man who had developed additional symptoms (optic neuritis, hemianopia, etc.) actually during the time he was being energetically treated for a gumma. Recourse was then had to operation, and a small, very fibrous gumma was removed. Dr. Collier pointed out that gummata should be sharply divided into two classes—(1) rapidly growing diffuse growths presenting clinically two characteristic features—acute onset and general symptoms (headache, vomiting, and early optic neuritis). These cases respond well to anti-syphilitic remedies. Many of them are really cases of acute hydrocephalus due to syphilitic ependymitis. (2) Slowly growing tumours characterised clinically by the presence of facial symptoms (epilepsy, etc.), and by the late development of optic neuritis and other general symptoms. This late development of general symptoms was probably due to changes in the vicinity of the gumma. The present case belonged to this group. Many of these cases also responded well to medicinal treatment, but some did not. He emphasised the fact that the cases not responding to medicinal treatment usually belonged to the second group, and could be localised so that operative treatment was clearly indicated.

Sir VICTOR **HORSLEY** concurred in all Dr. Collier's remarks, and narrated a case throughout similar to the one described by Dr. Collier.

Dr. PURVES **STEWART** raised the question of the duration of medicinal measures, and stated that examination of the cerebro-spinal fluid for lymphocytosis was important, as sometimes this sign was present—indicating a syphilitic nervous affection—when no other symptoms revealed the presence of the lesion. Thus treatment should be continued not only until the symptoms disappeared, but also until the lymphocytosis subsided.

Dr. FARQUHAR **BUZZARD** agreed with Dr. Collier that some cases even of the second group recovered with medicinal treatment.

Drs. F. E. **BATTEN** and GORDON **HOLMES** read a paper on

THE NERVOUS SYSTEM OF A DOG SUFFERING FROM ATAXIA AND INVOLUNTARY MOVEMENTS.

The animal has had choreic movements, failing vision and smell, apathy and marked mental deterioration. At post-mortem was found: cell infiltration of the perivascular region, the cells being lymphocytes and plasma cells. The changes were strongly reminiscent of those found in general paralysis of the insane, except that the ganglion cells were but little altered.

Sir VICTOR **HORSLEY** pointed out the similarity of the changes to those found in rabies.

Dr. T. GRAINGER **STEWART** read a paper on

FOUR CASES OF TUMOUR OF THE FOURTH VENTRICLE.

These cases were very difficult to recognise, and one had chiefly to rely on the absence of signs indicating positive or cerebellar disease. He laid stress on the sudden onset of the symptoms, the fact that there was giddiness which increased on movement, and on the slow, coarse nystagmus, equally marked in both lateral directions; death was often sudden.

Dr. DAVID **FERRIER** discussed the symptomatology.

Dr. F. E. **BATTEN** referred to a case in a child with whom vomiting was the only symptom.

Dr. S. A. K. **WILSON** also referred to a case. It was characteristic of these lesions that the symptoms till near the end were only general.

Dr. FARQUHAR **BUZZARD** read a paper on

A CASE OF TUBERCLE OF THE SIXTH NUCLEUS ON ONE SIDE.

The patient, a woman æt. 42, had had signs of tumor cerebri, and then died of tuberculous meningitis. At the autopsy was found degeneration in the posterior longitudinal bundle on the opposite side to the lesion of the sixth nucleus. According to Bruce this bundle does not cross the middle line in its course, and this case might be adduced as indicating that it reached the opposite third nucleus by crossing immediately on leaving the sixth nucleus. It was not conclusive, however, for the degenerated fibres might have originated, not in the sixth nucleus, but in Deiter's nucleus.

Sir VICTOR **HORSLEY** was of opinion that the degenerated fibres certainly came from Deiter's nucleus, which in his opinion was to be regarded as the centre regulating conjugate movement, and not, as previously thought, the sixth nucleus.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, NOVEMBER 22ND, 1907.

The President, Dr. A. R. **PARSONS**, in the Chair.

VILLOUS TUMOUR OF THE BLADDER.

DR. **BOXWELL** stated that the patient from whom the specimen was taken was a young man, aged about 34, who had been perfectly healthy until about 12 months previous to his admission to hospital. The chief symptoms on admission were hæmaturia with pain on, and increased frequency in, micturition. The urine was found to be alkaline, full of pus, and in addition contained triple phosphates, epithelium, and a considerable amount of blood. The appearance of the man, and the fact that he had lost his voice, suggested that the trouble was of tuberculous origin, but no tubercle bacilli could be found in the urine. He was too ill to be operated on, and even attempts to wash out his bladder were always attended with great pain. He died a fortnight after admission to hospital. At post-mortem the base of the bladder was found to be occupied by several large villous masses, the largest being situated at the mouths of the ureters; the bladder wall was thickened, and the ureters greatly dilated. The kidneys showed the ordinary septic changes following cystitis.

Mr. L. G. **GUNN** spoke on the subject.

CARCINOMA FOLLOWING ULCER OF DUODENUM, WITH SECONDARY DEPOSITS IN LUNGS.

Dr. **BOXWELL** exhibited specimens with microscopic slides. The organs were obtained from a man æt. 60. He had been suffering for some years from attacks of jaundice, sometimes with slight vomiting, but never had much pain. An exploratory laparotomy was performed, and the gall-bladder was found to be distended, and a hard mass could be felt in the duodenum, while the pancreas was found filled with small hard nodules. The patient made no definite progress, and died in a week. At post-mortem it was found that there was something like an ulcer occupying the ampulla, just at the entry of the common duct, with a fair amount of new growth of a cancerous nature around it. Nodules were also scattered through the lungs; these were found to be carcinomatous, while the nodules in the pancreas were merely necrotic masses. The liver was simply jaundiced; there were no secondary deposits in it.

CANCER OF THE BLADDER.

Mr. L. G. Gunn exhibited a specimen showing extensive cancer, filling practically the whole interior of the bladder. The patient was a man who presented all the appearance of a very acute inflammation of the bladder. When the patient was first seen the disease was too far gone to allow of operative interference beyond giving relief by draining; the tumour was then about the size of a small tangerine orange. The man lived about two months, and in that time the bladder had filled up. The tumour was a very cellular carcinoma, and was unusual in not having any symptoms of hæmorrhage.

THROMBOSIS OF ARM WITH GANGRENE.

Dr. O'Carroll described a case of gangrene in a widow, æt. 39, who entered hospital in July last complaining of cramps in the fingers of her left hand. The day after admission a slight bluish tinge was seen, especially about the wrist, and she was unable to lift the forearm. Nothing in her history gave any clue to the cause of the condition. Her heart was found to be rather weak, with some slight softening of the first sound. The only objective defect to be found was a small quantity of albumen in the urine. Her chest was small; she was thin, and had a ruddy blue face. The day after admission pain was complained of in the right hand and arm, and a slightly black hue was found about the right wrist. Within a few days the circle moved up the left arm, while the right hand cleared up. The left hand gradually dried up, and became perfectly rigid, and in about three weeks the dryness and mummification had reached the junction of the upper and middle third of the forearm. The arm above this became swollen and tender, and presently a line of demarcation occurred, and sank in about a fortnight to a depth of about half an inch. The patient was given two or three minutes of anæsthesia, and the arm was taken off above the elbow joint. The stump healed perfectly, and she left hospital much better in general health.

Mr. H. Stokes referred to a somewhat similar case.

Professor White said he remembered quite well the case referred to by Mr. Stokes, which was so like that which Dr. O'Carroll had so graphically described. In it the gangrene was undoubtedly due to the condition of the vessels of the arm, which were rigid, and their lumina almost obliterated.

SARCOMA OF TIBIA.

Dr. G. Harvey showed a specimen of sarcoma of the tibia occurring in a married woman æt. 55. He exhibited at the same time several microscopic slides and X-ray photographs of the tumour. The latter showed certain points which were not evident in the specimen—viz., (1) that the fibula was free from the growth, (2) that there was no great expansion of the medullary cavity, but (3) there was great rarefaction of the head of the tibia, and (4) that the articular surface of the tibia was enlarged at its external margin. The growth did not appear to infiltrate the muscles very much, but rather pushed them in front of it. Microscopically, the tumour was in parts an ossifying chondro-sarcoma. In other portions round cells in alveolar grouping were to be seen. Two interesting questions arose: First, was this alveolar arrangement due to a segregation of cells into cartilage spaces, with partial absorption of the cartilage?—and might this be the general explanation of alveolar sarcomas, using the term in the descriptive sense? Second, did the sarcoma start in the centre of the bone or outside? From the appearances of the radiograms in conjunction with the fact that the tumour cells appeared to be grouped about the perichondrium, he inclined to the view that the growth originated outside the bone, probably from the cartilage of the point.

Professor White said he thought the appearances seen in one of the X-ray photographs were strongly in favour of the view that the tumour started inside the bone. The upper portion of the internal aspect of the tibia was completely destroyed, which simply meant that the tumour in making its way out destroyed the bone. The so-called expansion of bone simply meant that while the bone inside was being infiltrated and destroyed, new bone was being formed outside. A time always arrived when the new bone was not formed in sufficient quantity to cover the more rapidly growing tumour.

Mr. L. G. Gunn also spoke, and Dr. Harvey replied.

LARYNGEAL SPECIMENS.

Professor White showed and demonstrated a few interesting old specimens from the College of Surgeons' Museum.

(*a*) *Cases of Hanging.*—In two specimens obtained about 80 years ago the same lesions were present. In each case the thyroid cartilages and os hyoides are widely separated from each other—the intervening muscles, etc., having been almost completely torn across. The epiglottis was torn away from rest of larynx, and ascended with os hyoides and tongue into floor of mouth. In Vol. V. of the old *Dublin Hospital Reports*, a short description of these specimens is given. It would appear that the omo-hyoid, sterno-hyoid, and sterno-thyroid muscles were lacerated in such a fashion that only a few shreds held the torn portions together. The right sterno-mastoid was ecchymosed, contused and broken; while the left sterno-mastoid was but slightly bruised. The rope knot was to the left side. The skin alone intervened between the rope and the interior of pharynx. The cervical vertebræ and spinal cord were uninjured.

(*b*) *Suffocation.*—The specimen in this case showed a large lump of meat, almost three inches in length, firmly wedged in the pharynx and œsophagus, and completely closing the superior opening into larynx.

(*c*) *Ulceration of Tracheotomy Tube into Aorta.*—No history attached, but apparently the condition for which the operation of tracheotomy was performed was an acute one, as no disease of the larynx is recognisable. At a period long after the operation, but some time antecedent to death, some unskilful person attempted to replace the tube, but thrust it instead between the sternum and trachea, with the result that ultimately the lower end of tube ulcerated into arch of aorta. Judging from the appearance of the wound in the trachea, some time must have elapsed before this occurred. From the time the tube was put in the false position, the patient must have breathed in the ordinary way, as the tracheal wound was quite blocked by the tube in front.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held December 4th, 1907.

The President, Dr. James Ritchie, in the Chair.

Dr. W. G. Aitchison Robertson gave a demonstration of the method of sterilising milk by Buddisation. He referred to a previous communication concerning the state of the milk supply of Edinburgh, and said that the condition of matters had in no way altered for the better during the two years which had since elapsed. Budde's method of sterilising milk had proved commercially successful in Denmark, and a company had been formed to supply Buddised milk in Edinburgh. He did not himself believe that in the minute quantities which were required to destroy the germs in milk such preservatives as formalin or boric acid were deleterious, but any objection which existed to their use did not apply to Budde's process. He had found the germ content of Edinburgh milk higher than the standard of good quality in many cases. Buddisation consisted in adding peroxide of hydrogen (pure 3 per cent. solution) to milk at a temperature of 120° F. The enzymes, which are present in milk as well as all other living substances, decomposes the peroxide of hydrogen and sets free nascent oxygen, which acts as a germicide. In order completely to sterilise milk, .03 to .035 per cent. of hydrogen peroxide is added. This quantity is completely decomposed by the milk, and consequently there is no disagreeable taste. Milk so treated will remain sterile for a number of days. Mr. Budde, who was present, gave details of his process, and samples of the milk were on view, stored in the automatically stoppered bottles in which it is supplied commercially.

Dr. **Alex. Goodall** and Miss **Isabel Mitchell**, B.Sc., read a paper on

THE ACTION OF CERTAIN SALTS OF FORMIC ACID ON THE CIRCULATORY AND MUSCULAR SYSTEMS,

a full abstract of which will be found on page 634.

In the discussion that followed,

Dr. G. A. **Gibson** remarked that, from the results of clinical observation, he could not doubt that formic acid had a marked effect in raising the blood pressure. This he had frequently demonstrated in cardiac disease by means of the Riva-Rocci sphygmanometer. He was also convinced that in chorea the drug had a valuable tonic action on the muscles. Moreover, he believed that it was of use as a tonic. He had frequently noticed that patients who had felt the benefits of formic acid asked for more of the same tonic, though they were ignorant of its composition.

Dr. C. B. **Ker** also spoke favourably of its use in diphtheria. The mortality rate had diminished slightly since they had begun to use it systematically in the fever hospital, and the incidence of post-diphtheritic paralysis had diminished. Possibly the lessened number of cases of post-diphtheritic paralysis was due to the action of formic acid on muscular tissue. At present, in spite of Dr. Goodall's destructive criticism, he was inclined to go on using a remedy which was giving him good results. It was generally said that formic acid was apt to disagree, but he had noticed that in cases of cardiac vomiting, when nothing else could be retained except a little iced brandy, formic acid was well borne. In his cases diuresis had not been noticed.

In his reply Dr. **Goodall** spoke of the difficulty of reconciling clinical and physiological discrepancies. He had made no observations on the action of formalin on the metabolism, because he understood that the subject was being worked out elsewhere at present.

Mr. J. W. **Struthers** read a paper on

THE VALUE OF NOVOCAIN AS A LOCAL ANÆSTHETIC FOR SUBCUTANEOUS USE.

Novocain was a synthetic local anæsthetic which had already found many supporters, and the claims made for it were, he thought, well founded. After trying it in about 85 cases, he could say that it had proved uniformly satisfactory, and equal to, if not better than, cocaine and eucaine. It was soluble, stable, and sterilisable, and compatible with adrenalin. He preferred to make up a stock solution in bulk which was boiled each time before use. For infiltration anæsthesia he used a solution of 1.400, with 1 minim of commercial adrenalin solution added to every 2 drachms. This solution produced anæsthesia in about 10 minutes, and it lasted for from one to three hours. For inguinal anæsthesia, produced by injecting novocain in the neighbourhood of large nerve trunks, a stronger solution (2 per cent.) was employed, with 1 minim of adrenalin added to every drachm. The maximum dose of the weaker solution was 6 ozs.; of the stronger, ½ oz. A number of operations, such as avulsion of the nails, amputation of the fingers, cleansing lacerated wounds, incision of whitlows, etc., which had been satisfactorily performed under novocain, were referred to.

Mr. **George Chiene** and Mr. **Wheeler** (Dublin) discussed the paper, the former pointing out the great advantage of local anæsthesia in minor surgery. Fatalities from the anæsthetic were relatively far more common after minor operations, therefore general anæsthesia should as far as possible be dispensed with. Mr. Wheeler confirmed Mr. Struthers' estimate of the great value of novocain, and described his method of employing it. He injected it into the true skin, and found that anæsthesia was almost immediately produced.

In reply, Mr. **Struthers** said that while anæsthesia was almost instantaneous when the injection was made into the true skin, he preferred to give it subcutaneously, which delayed the action somewhat.

Dr. **Alexander James** read

NOTES ON CASES OF TUBERCULOUS ANÆMIA.

The condition had first been described by Trousseau; its characteristic was that along with the symptoms and appearance of anæmia there was found an almost normal appearance of blood. He gave notes of two cases in which the patients had complained for some time of pallor, palpitation, and breathlessness in exertion. They both looked markedly anæmic, but on examination of the blood an almost normal count was found. On further investigation evidences of phthisis were discovered. It was argued that the existence of chronic anæmia, without alterations in the blood, was suggestive of tuberculosis. Possibly, the anæmic condition was a factor in the development of the tuberculous diathesis. It was possible that the appearance of anæmia was actually due to a diminution in the total volume of the blood, and was associated with a condition of hypoplagia of the vascular system. Trousseau held the view that in these cases treatment of the anæmia was not very safe; he compared the need for care in giving of iron to these patients with the caution which must be exercised in checking leucorrhœal discharges, and in operating on fistula in tuberculous patients. It seemed to him that hæmorrhage from the lungs might develop on the administration of iron. With this old-fashioned view Dr. James to some extent agreed, and he quoted an example of the occurrence of signs of tuberculosis after treatment of an anæmia of this description with arsenic.

Dr. **Gulland** discussed Dr. James's paper.

Dr. **Alexander Bruce** read a paper on

UNUSUAL SEQUELÆ OF HERPES ZOSTER (?) POSTERIOR POLIOMYELITIS.

The patient in question had suffered from a severe attack of herpes zoster, followed after a short interval of time by a sensation of numbness, which passed up one lower extremity and down the other. Then followed muscular weakness of the right leg, with exaggeration of the deep reflexes and an extensor plantar response, and loss of pain and thermal sense with conservation of the lactile and muscular sense below the level of the herpetic zone. The secretion of sweat was also abolished over the affected limb. These symptoms—dissociated anæsthesia, muscular weakness, and exaggeration of the reflexes—subsequently spread to the left leg, and these gradually cleared up altogether. The sequence of events was suggestive of hysteria, but Dr. Bruce gave reasons for supposing that they were due to a hæmorrhage or other vascular lesion at the base of the posterior cornua, first on one side, and then on the other, a condition of posterior poliomyelitis

---

CENTRAL MIDWIVES' BOARD.

Meeting held Thursday, November 28th, 1907.

The President, Dr. **Champneys**, in the Chair.

After a brief discussion as to the correctness of the designation of "midwife," and of the inability of the Act to suppress the practice of so-called "maternity nurses," it was agreed by the Board—(*a*) That the Home Secretary's proposal to extend the system adopted for reporting convictions of midwives within the area of the London County Council to the whole of the Metropolitan Police District, if desired by the other County and County Borough Councils therein, be accepted, with thanks; (*b*) that it be suggested to the Home Secretary that this system might with advantage be extended to the whole of England and Wales; (*c*) that the Home Secretary be furnished with particulars as to those Local Supervising Authorities who have not complied with Section 8 (5) of the Midwives Act, 1902, up to the present time.

A letter was read from Dr. W. P. T. Daniel, of 273, Cable Street, London, E., forwarding a copy of a resolution adopted at a meeting of medical men residing in the parish of St. George's-in-the-East, and neighbourhood, declaring their intention, after November 30th, not to proceed to any case of parturition, etc., occurring in the parish, on the requisition of a midwife, unless a minimum fee of one guinea is guaranteed either by the Guardians or by the Central Midwives' Board.

It was agreed—(*a*) that a copy of the correspondence be sent to the Privy Council, pointing out the difficulties and dangers of the situation, and suggesting that a copy of the Local Government Board's circular on the subject should be forwarded to every medical practitioner in England and Wales; (*b*) that the Board's action in the matter be communicated to Dr. Daniel, and that he be informed that the Board has no power to pay fees in such cases.

THE FEES OF MEDICAL MEN SUMMONED BY MIDWIVES.

Mr. Ward Cousins opened a discussion on the matter, reporting the question which had been put to him by the Royal College of Surgeons, as to what the Board was doing with regard to the question of the fees of medical men summoned to the assistance of midwives. He thought it was time the Board took some definite action. The whole efficiency of the Act was blocked by the absence of such official payment, and the consequent attitude of doctors. The Chairman said he thought the Board had done a good deal; it was out of their power to pay doctor's fees, or compel anyone else to pay them; but the importance of the matter had been constantly urged by them before the authorities, and he pointed to the recent circular issued by the Local Government Board, and sent to all the Local Supervising Authorities as a result of this agitation. He had great hopes from this circular, but it was quite new, and he thought it highly probable that a great many practitioners did not yet know of it. Dr. Stanley Atkinson said that St. George's-in-the-East was the only parish in London which had objected to complying with the suggestion of the Local Government Board.

Letters on the same subject had been received from Dr. E. Rowland Fothergill, Hon. Secretary to the Wandsworth Division of the Metropolitan Counties Branch of the British Medical Association, and from Dr. J. W. Hembrough, County M.O. for Northumberland. It was decided that the latter should be forwarded to the Privy Council.

At the request of the Local Supervising Authority for the Worcestershire County Council, it was agreed that Birmingham be constituted one of the Provincial Examination Centres during the pleasure of the Board.

Letters had been received from the Clerks to the Guardians of the Ashton-under-Lyne and Gateshead Unions, inquiring the reasons of the Board's refusal to approve their Union Hospitals as Training Schools for Midwives.

It was agreed that the Guardians be informed that the decisions were arrived at after a full consideration of all the facts bearing on the matter, and that it is contrary to the practice of the Board to give reasons for its decisions in such cases.

At their own request the names of 12 women were removed from the roll, on the grounds of old age, ill-health, or inability to comply with the rules.

Vacancies on the list of examiners to the Board were filled by the appointment of :—(1) J. P. Hedley, M.B., B.C. (Cantab.), M.R.C.P., Obstetric Tutor and Registrar, St. Thomas's Hospital; (2) Eardley Holland, M.D., B.S. (Lond.), F.R.C.S., Obstetric Registrar and Tutor, King's College Hospital, Assistant Surgeon for Diseases of Women, Metropolitan Hospital.

Applications for approval as Teacher were granted to the following:—Rosa E. Bale, L.R.C.P., L.R.C.S.; W. Fordyce, M.B., F.R.C.P.E.; F. G. Haworth, M.B.; G. F. B. Simpson, M.D., F.R.C.S.E.; S. H. Smith, M.B.; and of Penrose Williams, M.R.C.S., L.R.C.P.

Five midwives were approved to sign Forms III. and IV.

Dr. Stanley Atkinson was added to the Finance and Office Committee.

In the Secreary's report of the October Examination it appeared that out of a total of 461 candidates, 386 passed, leaving the percentage of failures 16.27. The London Training Schools had sent up 128 candidates, of whom 120 were successful. From the rest of the training schools in England, Wales, Scotland and Ireland there were 245 candidates, of whom 47 failed. The number of candidates trained by private tuition was 88, out of which 68 passed the examination.

The next general meeting of the Board will be held on December 19th, at 2.45 p.m.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Dec. 7th, 1907.

COLLOIDAL SILVER.

After a silence of several years, colloidal silver is once more placed on the *tapis*. Netter, in 1902, was the first to bring it under the notice of French surgery in an important communication made to the Medical Society. It was spoken of for some time, and finally fell into oblivion. Some medical men, however, continued to use it. Recently, some articles of Victor Henri and Iscovesco on colloidal silver, prepared by electricity, once more drew attention to this agent, and at the late Medical Congress several communications were made on the subject, presenting it in a very favourable light.

Silver can, like several other metals, such as mercury, gold, be obtained in a colloidal state. The reduction of salts of silver by different agents produces very easily colloidal solutions, but chemical processes give, all of them, impure products.

The electric preparation of colloidal silver, on the other hand, according to the method of Brédig gives absolutely pure products. Faraday proved that if an electric spark was given off in the air between two gold wires, a metallic deposit was obtained under the form of a very fine powder. It was by taking this principle as a basis that Brédig prepared a large number of colloidal metals.

The metallic solutions thus obtained, says Dr. Milian, are coloured more or less; they are clouded and yet leave nothing on the filter, nor with an ordinary microscope can any solid deposit be detected. With a powerful lens, however, a large number of brilliant particles can be seen, moving with great rapidity, and which are the metallic granules in suspension in the water.

One of the most important properties of these pseudo-solutions is that of giving a precipitate by an electrolyte of no matter what kind, provided it is employed in sufficient quantity; thus chloride of sodium precipitates a solution of colloidal platinum, and nitric acid precipitates silver colloidal.

Colloidal silver, called by Crédé collargol, appears under the form of small black grains easily crushed. It is employed in ointments, subcutaneous or intravenous injections.

The strength of the ointment is 15 per cent. It is utilised in the form of frictions like mercurial ointment. The skin being previously washed, the ointment is rubbed in for about ten minutes. These frictions possess a certain activity of absorption, but they are insufficient in grave cases. Subcutaneous injections should never be employed, as the solution (1—25) is absorbed very slowly, leaving hard nodules which take several days or weeks to disappear. The same might be said of intra-muscular injections.

Intravenous injections should be always preferred. Here absorption is rapid and complete. When the injection is properly made it leaves no trace, and its action is rapid and powerful.

The solution may be that of colloidal silver dissolved in water (1—100), but Dr. Milian prefers to employ electrargol, that is to say, collargol prepared by the electric method, as it is more active and more fluid.

The instrument employed is a syringe holding two drachms, as it may be necessary to inject that amount.

The bend of the elbow, where the veins are most visible, is the region to be chosen for the injection, and the preliminary preparations are those for blood letting: a bandage around the middle of the arm to arrest the venous circulation, antisepsy of the part by soap and hot water, and finally, with proof spirit. The operator, his hands being also rendered aseptic, seizes the needle, and only the needle between the thumb and index of the right hand, while with the left hand he fixes the vein by pressing on it with the thumb, he inserts it obliquely and gently into the vein. He knows he is in it by a drop of blood flowing out of the needle when he continues to push it in parallel to the vein. Then, holding the needle in the horizontal position, he fixes on to it the syringe and slowly injects the contents. No resistance should be felt during the injection, which if experienced, would result either from the needle being blocked up or that the liquid had penetrated into the cellular tissue. In either of these cases the operation should be stopped, the needle withdrawn and re-inserted into another vein.

These injections, made with the usual antiseptic precautions, are without danger; they are better borne than intra-muscular injections, and give truly wonderful results.

Asthma and Atropine.

Some 70 years ago, Trousseau recommended atropine in the treatment of grave cases of asthma, but this treatment fell into disuse, and yet deserves to be brought under notice again.

In a case of asthma of 20 years, for which different treatments had been applied in vain, including injections of morphia, atropine produced a prompt and durable effect.

The subjective condition improved, sleep returned, and the catarrh ceased. The treatment lasted six weeks. A quarter of a milligram was given twice a day at first, and gradually increased to two milligrams a day.

Certain very rebellious cases were not benefited, and sometimes troubles of accommodation and dryness of the pharynx were observed, but the heart was never affected. Naturally, the antispasmodic properties of atropine explain its action.

GERMANY.

Berlin, Dec. 7th 1907.

At the Medical Society, Hr. W. Braun spoke on

Penetrating Wounds of the Gastro-Intestinal Tract.

Last summer he had shown patients treated by himself in the Friedrichshain Hospital; first, two children with punctured wounds of the abdomen, victims of a crime that had aroused a great deal of excitement. One child, three years of age, had three penetrating wounds of the abdomen, from which intestine protruded, and in which the intestine was wounded in no less than eight places. In the other case, a child of five, the omentum protruded, but the intestines themselves were intact. To these were added four patients with gunshot wounds of the abdomen. In one case, that of a young girl, the bullet had penetrated from behind, had wounded the lower pole of the right kidney, and had then passed through the stomach, duodenum, and liver. The stomach and bowel were closed by suture; the kidney had to be extirpated on account of the continued bleeding that could not be arrested. Another patient who had severe injuries of the gastro-intestinal tract inflicted on the same occasion died. Two boys, aged 6 and 15 respectively, recovered.

The surgical experiences of the last war showed that in the case of abdominal wounds received from firearms in the field, expectant treatment gave the best results. The best war results were, however, wretched as compared with those obtained in a state of peace. Here it was decidedly better to treat at once, and the sooner the better. Undoubted signs of injury of intestine, such as vomiting, blood in the stools, or escape of fæcal matter from the abdominal wound, were not necessary, and in the cases shown were not present; but, on the other hand, symptoms of peritoneal irritation, such as nausea and abdominal tension, were present in every case. Where there was a possibility of a penetrating wound of the abdomen, the case should be attacked at once, provided the patient was in a properly equipped hospital. On widening the track of the wound, whether of knife or bullet, one can easily see whether the peritoneum was wounded or not, and in any case no harm would have been done.

Immediately on the infliction of the injury, spasm of the bowel took place; that at first closed the bowel and prevented the escape of fæcal matter; paralysis of the bowel did not take place till later, and then the escape of fæces was facilitated. Therefore, operation should not be delayed till the first shock was passed. Waiting might be very fateful for the patient, for the reasons that, first, the danger of peritonitis would be the greater the more abdominal contents had escaped, and, next, that suture of a well-contracted bowel was much more reliable than that of a paralysed one.

At the Otological Society Hr. Wagner showed a child in whom during the course of an attack of inflammation of the middle ear symptoms present in the fundus oculi were the main cause for chiselling the mastoid. The patient, a girl, gave the impression of being very ill, although both pulse and temperature were normal, and there was no tenderness over the mastoid. In the fundus oculi both the arteries and veins were engorged, and there was papillitis on the left, but no papillary stasis. At the operation a perisinuous abscess the size of a small hazel nut was found, and which was undergoing considerable pressure. After the operation the papillitis became still worse, but the vascular engorgement receded at once. Körner attributed this papillitis to a meningo-encephalitis.

Hr. Oertel related a case of

Serious Injury to the Skull.

The head of a little boy, æt. 3, was crushed between a mangle and the wall. The left side of the face at once became paralysed. A considerable quantity of blood escaped from the nose, mouth, and right ear for the next two days. After that, watery fluid came from the same ear, and a fortnight later pus flowed profusely. The external auditory canal was narrowed up to a small slit, out of which pus flowed when the child cried. Pressure on the mastoid, which was tender, also caused pus to flow from the opening.

An operation showed that a fracture had taken place in the lower portion of the squamous bone, and that a sequestrum, the size of a sixpenny piece, lay in the posterior wall of the auditory canal and was only connected with the other bony parts by a narrow bridge of osseous structure. The removal of the sequestrum led to speedy recovery from the traumatic mastoiditis. The left-sided facial paralysis was also beginning to disappear.

AUSTRIA.

Vienna, Dec. 7th, 1907.

Osteopathy.

Goldreich showed a child with an uncommon form of osteopathy due to syphilis, as was presumed at the May meeting, when he showed the child before treatment in the morbid state. At that time the differential diagnosis resulted in designating the case one of inhibited ossification, or osteogenesis imperfecta remotely depending on hereditary syphilis. At that time the ossification of the cranium was quite rudimentary, while there was inflammatory hyperostosis of the long bones which strengthened the syphilitic view. The same virus was considered active in stopping the growth of the flat bones of the cranium by some of the members, while others argued the opposite—that inflammatory hyperplasia was the rule in the bones of the head as well as the bones of the limbs. A more exhaustive examination revealed osteochondritis in the shoulder-blades and the elbow-joints, with pseudoparesis of the right arm.

After that examination the child was put on antisyphilitic treatment, with magical results, putting beyond doubt the proof that the affection was entirely due to the syphilitic virus.

The cranial defects soon closed, and the inflammatory hyperostosis of the long bones disappeared. It was subsequently discovered that the father had suffered from syphilis.

Spieler said he had a similar puzzling case two years ago, which he recorded in the *Zeitschrift*, and diagnosed it as probably due to hereditary syphilis.

Hochsinger said he had no doubt that the case was one of hereditary syphilis, as osteogenesis imperfecta, hyperostosis, etc., were peculiar to congenital syphilis.

Escherich thought that those belonging to osteomalacia were of a similar origin.

Cerebellar Tumour.

Marburg presented a case that originated a year ago in disturbance of vision, pain in the head of a rheumatoid character, unsteady gait, great increase of cranium, and a general growth of fat throughout the body. There was also congestion of the papilla and ataxia present. The tumour seemed to be located about the anterior portion of the superior vermiform process, causing dropsy of the third ventricles and degenerative changes in the hypophysis, the latter morbid condition accounting for the adipositas universalis, which has amply been demonstrated in cerebral changes.

Hochwart drew attention to the happy, gay, unconcerned state of the patient's mind, which he said was characteristic of cerebellar tumours.

Poliomyelitis.

Zupper next brought in a six-year child, with paralysis of both arms, including the shoulder muscles, with the exception of the levator scapulæ, trapezius and serratus magnus. All the muscles of the arms were paralysed with the exception of the flexor carpi ulnaris and flexors of the fingers. On the right hand the flexor of the thumb was also intact.

From this state it must be assumed that the lesion in the anterior horns of the cord cannot extend above the fifth, sixth, and seventh cervical vertebræ; but it must be noted the supra- and infraspinatus are involved in the general destruction, which have part of their origin in the fourth segment. This is worthy of note, as the phrenic nerve has its origin in the fourth segment, and remains perfectly entire. Another freak may be observed in the musculus serratus magnus, which arises in the fifth segment and is functionally entire. This case forcibly demonstrates how difficult it is to locate lesions of the cord with any approach to accuracy. Zappart said the prognosis was very unfavourable, even by orthopœdic means, although by a form of arthrodesis in fixing the shoulder and elbow, the boy could be made to raise the one hand to the mouth by the assistance of the other.

Moszkowicz thought a good deal could be accomplished in this case by means of surgical-orthopœdia, and exhibited a similar case he had operated on to demonstrate his assertion.

Abnormal Displacement.

Hochsinger interested the members with an unusual displacement of the heart below the ribs altogether, where the apex beat could be seen on the left side in the abdomen, while the upper margin of the cardiac area was delineated between the fourth and fifth ribs; towards the right the margin was two finger-breadths outside the sternum. Systolic and diastolic murmurs were found at all the ostia.

It appears that after an attack of endo- and pericarditis rheumatica, a mediastinal pericarditis supervened, fixing the pericardium to the anterior costal wall. The valvular defects and concretions subsequently caused hypertrophy and dilatation, but being fixed in its upper margin left no other retreat for the expansion than downwards and to the left in the abdomen, pressing the diaphragm before it into the abnormal position as seen in the patient.

HUNGARY.

Budapest, Dec. 7th, 1907

Physostigmine in Intestinal Paresis.

Not so long ago atropine was praised highly in all cases of intestinal obstruction depending upon paresis of the intestines. However, the director of the First Internal Clinic in Budapest, Prof. Koranyi, holds that physostigmine is much more suitable for such cases. Similar opinion was expressed also by Dr. Dollinger, Professor of Surgery. The latter gave in one instance where operation was refused and atropine given without the slightest effect. The patient was getting weaker and weaker, but after a subcutaneous injection of half a milligrame of physostigmine, rapid improvement set in. In some cases it will be necessary to give as much as one milligrame. The drug is not suited for children, but does good service if given by mouth for nervous flatulency and atonic meteorism.

The Efficaciousness of the Erysipelas Serum.

Dr. Révérf having applied the antitoxic therapy in cases of erysipelas, describes the results of his investigations in the *Orvosok Lapja*. He used the blood serum obtained from patients convalescing from erysipelas. The doses used were generally 10 to 30 c.c., sometimes 68 to 90 c.c., hypodermically. Nine cases were thus treated, including erysipelas of the face. As the result of this form of medication, headache, delirium, and hallucinations disappeared. The appetite improved, and the temperature fell in the majority of cases. Whenever albuminuria was associated with erysipelas, the antitoxin caused the disappearance of the former.

On the Internal Treatment of Appendicitis.

Dr. Szèkàcs settles the confusing diversions of opinion as to the proper time for operation in appendicitis in a simple manner. In mild cases he merely applies linseed poultices and administers 0.50 gr. of collargol, 100 c.c. of water, a tablespoonful every half hour. In more severe cases the dose is increased to 1.0 gr. in 100 water, and Credé ointment is applied locally. The drug also may be given per rectum where vomiting interferes. Sometimes a cure follows even where peritonitis has already set in, and of a large series of cases only two were lost since the peritonitis had already advanced too far when the patients were seen for the first time. Surgical intervention is only indicated where there is general peritonitis, and in these cases it is advisable to establish an artificial anus, and also to give large doses of collargol. This drug is harmless even if applied in very large doses.

The Sterility of Women.

Dr. Bäcker discussed the various forms of sterility in women at the last meeting of the Royal Interhospital Association. He cautioned his colleagues against the tendency to go ahead with the treatment of sterility on the assumption that it is due to the woman. In every case, he believes, the husband should be questioned as to his virile power, and a careful examination of his sperma should be made. This search for spermatozoa should be made several times, and at rather long intervals, during which time the person is to abstain from intercourse, since it is well-known that a temporary azöospermia occurs after repeated coitus. Dr. Bäcker read a report concerning 483 cases of sterility, in 58 of which absence of spermatozoa has been found. In nineteen of these cases the wives had been under treatment. Furthermore, he found in 37 instances persistent oligo-spermia, and 13 times necrospermia.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Treatment of Incipient Insanity.—Dr. Urquhart, the superintendent of James Murray's Royal Asylum, Perth, has written a letter to the *Scotsman* strongly supporting Dr. Clouston's appeal for the establishment of wards for the treatment of mild mental disorder. He instances the experience of the Albany Hospital, N.Y., in which on the petition of some physicians, a psychiatic pavilion was erected in 1902. It is a two-storeyed building containing 24 small rooms, 6 day rooms, and 2 dormitories, and since it was opened 1,031 patients have been admitted. Of these, 596 have returned to their homes recovered or improved, 316 have remained stationary, and 86 have died. More than half the patients were returned to their homes without the formidable apparatus of legal procedure, and the institution has become a general hospital turning none who are sick from its doors.

Proposed Model Hospital for the Scottish Exhibition.—In connection with the National Exhibition, which is to be held in Edinburgh next year, a letter was read at the last meeting of the Managers of the Infirmary, stating that it was proposed to have a home nursing section in connection with the woman's section of the exhibition. Lessons will be given in home nursing and the use of disinfectants. A request was made that the lady superintendent of the infirmary should be permitted to co-operate with the Exhibition Committee in arranging this exhibit. The letter was remitted for consideration.

Edinburgh Medico-Chirurgical Society. — An interesting meeting of this society was held on Wednesday last, when Dr. Aitchison Robertson gave a demonstration of the method of sterilizing milk by Buddisation; Mr. Budde, who was present, gave details of the process, and exhibited samples thus dealt with. The reading of papers followed, that by Dr. Goodall and Miss Mitchell on "The Action of certain Salts of Formic Acid on the Circulating and Muscular Systems" evoking considerable discussion. An abstract of this paper will be found in another column under the heading of "Original Papers." Mr. J. W. Struthers subsequently read a paper on "The Value of Novocain as a Local Anæsthetic for Subcutaneous Use," Dr. Alexander James one on "Tuberculous Anæmia," and Dr. Alexander Bruce one on "Unusual Sequelæ of Herpes Zoster." A report of the proceedings will be found under the heading of "Transactions of Societies."

BELFAST.

Queen's College.—The successful attainment of the objects for which the Better Equipment Fund was raised was marked by an interesting ceremony at the College last week, when a fine bronze tablet commemorating the services to the Fund of the Rev. Thomas Hamilton, D.D., President of the College, was unveiled. The unveiling was done by Mr. Justice Dodd, an old classmate of Dr. Hamilton's, and the chair was taken by the Right Hon. Thomas Sinclair. References to the University question were made by both these gentlemen, and hopes were expressed that the College might before long become autonomous.

Lurgan and Public Health.—A largely attended meeting was held in Lurgan last week, when it was decided to start a local branch of the Women's Health Association of Ireland. The inauguration of the new society will take place in connection with the visit of the Tuberculosis Exhibition to the town. Dr. Agnew, the Medical Superintendent Officer of Health, addressed the meeting.

Medical Inspection of School Children.—At the first meeting of the Public Health Committee of the Belfast Corporation, Dr. Henry O'Neill brought up the question of the desirability of having a system of medical inspection of school children in Ireland similar to that which is now coming into operation in England.

The Tuberculosis Exhibition.—In the course of the past fortnight, during which the Tuberculosis Exhibition was open in Belfast, it was visited by over 43,000 persons, and has proved in every way a great success. In the mornings and afternoons parties of visitors were conducted through the various rooms by young medical men who had volunteered for the duty; then afternoon lectures on sick-room cookery were given by a lady, and a series of evening lectures were delivered to crowded audiences. These lectures were as follows:—(1) Tuberculosis in Children, Dr. John McCaw; (2) Surgical Tuberculosis, Professor Sinclair; (3) Tuberculosis the Scourge of Ireland, Sir Robert Matheson; (4) Some Aspects of the Tuberculosis Problem in Ireland, Dr. David Lawson; (5) Stuffy Rooms: their Cause and Cure, Mr. Wm. Davidson, Belfast Technical Institute; (6) Tuberculosis in Animals, Professor Mettam; (7) How to Keep Our Homes Healthy, Mr. A. Savers, Belfast Technical Institute; (8) the Fight against Tuberculosis: what Other Countries have Done, Professor Lindsay; (9) the Prevention of Tuberculosis, Dr. Wm. Calwell; (10) Some Outstanding Effects of Tuberculosis, Professor Symmers; (11) Sanatorium Life Illustrated, Dr. Howard Sinclair. The exhibition was privately visited by her Excellency the Countess of Aberdeen, who made a special journey from Dublin for the purpose. She was conducted through it by the Honorary Secretaries, Drs. Thos. Houston and John MacIlwaine, to whom no small share of the credit for its success must be assigned.

Dr. Richard Barnett.—One of the oldest medical men in the district passed away last week in the person of Dr. Richard Barnett, who died in his sleep on his 79th birthday at his residence at Holywood, co. Down. Dr. Barnett studied in Edinburgh, where he graduated in 1849, and subsequently practised as a dental surgeon in England and the south of France, returning to his native city, Belfast, about 40 years ago, and practising here till his retirement in 1900. He was a singularly shy and retiring man, but came prominently before the public in two capacities, as a rifle shot and as a chess player, in both of which he obtained champion honours, as has his only surviving son, Mr. R. W. Barnett, a well-known member of the English Bar and of the Irish rifle team at Bisley. He was highly respected by his medical colleagues, and was for many years a vice-president of the Ulster Medical Society.

LETTERS TO THE EDITOR.

"THE BROWN DOG" DISTURBANCES.

Sir,—In your comment of November 27th *re* the "Brown Dog" and the students, you state the dog "was destroyed in a perfectly legal and regular manner." Allow me to correct this assertion. According to the Act of Parliament, "the animal must be killed immediately the object of the experiment is obtained." When this unfortunate dog, after an interval of two months, was opened a second time to ascertain if inflammation had been set up by the first operation, the object was obtained. But the dog was not killed; on the contrary, it was handed over, with wounds clamped with forceps, to a second vivisector, who performed upon it a severe operation lasting an hour. Even then it is a matter of doubt what further use may have been made of its mangled body, for at the trial a third person and also the laboratory boy both claimed to have despatched it. This may be "regular," alas! but it is certainly not legal.

I am, Sir, yours truly,
Frances E. White.

December 6th, 1907.

[We spoke simply of the death of the dog. It was killed in as legal and regular a manner as a bullock is killed in an abattoir. The plea about the second experiment done on the dog is beside the point altogether. It is mere juggling with words to make out that the demonstration given on the animal while it was under the anæsthetic and before it was killed was a transgression of the Home Office regulations. Would the anti-vivisectionists have preferred another dog to have been used instead?—Ed.]

To the Editor of The Medical Press and Circular.

Sir,—My attention has been called to a paragraph or two in an article in your issue of November 27th, *i.e.*, that "Animal experimentation provides the children of their borough" (*i.e.*, Battersea) "with the only means" (*sic*) "whereby they can efficiently be helped to recover when attacked by diphtheria." If you will take the trouble to look the matter up, carefully and without bias, you will find that some of the highest authorities, and perhaps, even especially vivisectionists, have by their expressed opinions traversed this misleading statement in your article. The rest of your article does not much concern me; but, in closing, I may say that your "Bullock" remarks will cause some astonishment in farming circles, proceeding from a pardonable want of knowledge of farming pursuits, operations, and objects. As regards your assertions about the different experiments on and death of the "Brown Dog" and the libel case to which you allude, it would be well not to confuse the two issues, and you might look this also up at the same time as you do the use of diphtheritic serum and certain farming operations.

Yours very faithfully,
George W. F. Robbins, Secretary.

Battersea General Hospital,
December 9th, 1907.

[We really cannot take Mr. Robbins seriously; to traverse his statements would be to do so. His advice to us to look up the literature of antitoxic serum in the treatment of diphtheria is a very poor joke. So, too, is his criticism of our knowledge of the castration of male animals on farms, and also of our delinquencies in the English language. With regard to the slander case in question, we are satisfied that a jury should have expressed their opinion of the veracity of anti-vivisection statements by awarding Dr. Bayliss £2,000 damages, and that the anti-vivisectionists proceeded to commemorate the occasion by putting up a public monument. A more striking testimony to the sense of truth and justice possessed by the organisers of the movement is hardly needed.—Ed.]

WHO INTRODUCED TRYPSIN?

To the Editor of The Medical Press and Circular.

Sir,—The letter from Dr. Shaw-Mackenzie, published in your last issue but one, contains a challenge as to the origination of the trypsin treatment of cancer that it will be impossible for the scientific world to ignore. The gentleman mentioned either is or is not the originator of the method. His statements are clear, and he has published the documentary and other evidence on which his claim is founded. On the other hand we have conflicting claims published for the most part in lay newspapers by Dr. Saleeby, a medical man, who asserts that Dr. Beard, a non-medical man, was the first to advance the theory. Dr. Shaw-Mackenzie states that he used trypsin and published a description before Dr. Beard. The matter can hardly be allowed to rest here, for some of our medical journals seem to have assumed that the honours do not rest with Dr. Shaw-Mackenzie. Surely no honourable man would decline his challenge to substantiate public statements as to the priority of claim.

Turning to another phase of the subject it seems curious that we should turn to Germany for information on the trypsin treatment, and quote freely the opinions of von Leyden on the point. We have no need for science "imported from Germany" while we have the original thing at home. Von Leyden is years behind Dr. Shaw-Mackenzie in this matter, yet we see von Leyden quoted copiously, while the prophet stands neglected in our midst. At present the scientific surgeons appear to be recognising that there is something of truth in Dr. Shaw-Mackenzie's patient investigations. It seems only reasonable to ask that the editors of medical journals should carefully examine the facts of the case before they accept the claims to priority on either side, especially when one of the rival claimants happens not to be a medical man.

Yours faithfully,
Onlooker.

London, W., December 8th, 1907.

THE MIDWIVES ACT.

To the Editor of The Medical Press and Circular.

Sir,—It is probable that most of us who have any knowledge of the ways and means of providing the poor with the proper care required when their children are being born will agree with the views expressed in the leader in the *Times* (December 7th); and it is quite clear that the Archbishop of Canterbury and Lord Balfour are perfectly incompetent to deal with this question. The *Times* seems to be at a loss to know what is best to be done. It thinks that it will be "necessary to appeal to Parliament for some modification of the stringency of the Act." It thinks that "the period has passed for any more waiting upon providence." This question is one that should and must be dealt with by our profession, and it would be interesting if you would take it up in The Medical Press and Circular.

I am, Sir, yours truly,
R. L.

PROPRIETARY MEDICINES.

To the Editor of The Medical Press and Circular.

Sir,—I heartily endorse every word contained in Dr. Hamilton's letter in your issue of December 4th. In May last I communicated a paper on "The Passing of the Prescription: some of its Causes and Effects," to the Therapeutical Society. The rules of that Society prevented me from publishing this paper in one of the weekly journals. At the present time it seems that the majority of the profession are simply playing into the hands of the manufacturers. As to these proprietary preparations, many of them are advertised in the daily and weekly newspapers at the expense of the profession, yet are largely ordered by the latter. Why medical men are such fools in their own interests I have never been able to understand. One thing is certain, that prescription-writing is greatly neglected in these days. Students are lectured on rare diseases, new and very often empirical modes of treatment, and intricate laboratory methods, but when they receive their diplomas they are often unable to recognise a common case of varicella or of rickets, and much less able to prescribe for such conditions. To put it broadly, the old-respected "family doctor" is going out of fashion, and a new order of "medical man," equipped with little more than a price-list of drugs put up in special forms, a book of recipes presented to him by some enterprising manufacturer, has sprung into existence. Such a state of matters is to be greatly deplored, but so long as medical men prescribe preparations that are advertised in the newspapers, and sold direct to the public, we cannot expect much else.

I am, Sir, yours truly,
James Burnet, M.D.

Edinburgh, December 5th, 1907.

MEDICAL LAW.

To the Editor of The Medical Press and Circular.

Sir,—The admirable editorials which appear with due frequency, and the letters of well-informed correspondents in your journal, ought by this time to have made your readers tolerably well acquainted with the state of medical law. Every one of your readers ought to know that very few clauses of the Medical Acts are of any practical value; that the penal clauses are in most cases useless; and that, when operative, there exists no authority charged with the duty of putting them in force. Prosecutions under Medical Acts never take place unless carried out entirely by private persons or by societies. It ought to be impossible under the present law for a quack to recover fees for professional services; but, as most County Court judges know nothing about medical law, it is not at all surprising, as in a case you report this week, to find a quack suing for fees and gaining his case in such a court. Quacks are, as a rule, too clever to need recourse to the law. They mostly get paid in advance, or take care to charge for "goods supplied," not for services. The goods may be a new nose, or an apparatus to make a crooked nose straight, an electric belt, or a certain cure for rupture in form of a truss; and if the patient consent beforehand to pay the sum agreed upon, it is probable that the law will in most cases help the quack to obtain the money, however exorbitant the charge. That medical law should remain in the shameful state in which it now stands must seem to outsiders disgraceful to the profession that tolerates it. Surely it is the duty of the profession to bring their case before the country and before Parliament. A Medical Law Reform Society, properly organised, and including the majority of those having valid claim to the title of leaders in the profession, would attract a very large amount of outside support. It would attract the support of the whole scientific world, of which doctors form so important a section; it would attract the support of lawyers, and in time, either by means of a Royal Commission or otherwise, the imperative necessity for new enactments would be brought home to the minds of statesmen capable not only of constructing the necessary legislation, but of placing it speedily upon the Statute-book.

I am, Sir, yours truly,
Common Law.

Lincoln's Inn, December 6th, 1907.

QUACK METHODS.

To the Editor of The Medical Press and Circular.

Dear Sir,—I would draw your attention to two pamphlets issued by "The Urillae Syndicate." Address, 31 and 32, King William Street, London, E.C.

To the Parochial Clergy.

Rev. and dear Sir,—The Urillae Syndicate ventures to send you the enclosed sample of "Urillae" in the anticipation and hope that you will make use of it in any suitable case coming under observation in the course of your visitation of the sick! It then goes on—

No restrictions with regard to diet are required; and total abstinence is not a *sine quâ non*.

A further sample will be sent on receipt of a stamp.

Then comes a second paper.—The Urillae Syndicate would deem it a great favour if particulars of cases were forwarded to 31 and 32, King William Street, London, E.C. Name, sex, age, address, occupation.

The above particulars will be treated as strictly private and confidential, and will in no event be made use of for advertising purposes.

1. Description of disease.
2. Duration of same.
3. How soon relief from pain was effected after first dose of Urillae.

These, Mr. Editor, are the essential points of these two extraordinary leaflets. You will notice that quackery has reached another stage, viz., that in which vendors of quack preparations are trying to create a further order of quack practitioners. Surely it is high time that we obtained our Royal Commission, and safeguarded the public against the experiments of unqualified practitioners.

Yours truly,
S. J. Ross.

Monkhams, Bedford.

OBITUARY.

CHARLES ROBERT DRYSDALE, M.D., St. And., M.R.C.P., F.R.C.S.

We record with sorrow the death of Dr. C. R. Drysdale, who passed away on December 2nd, in his 78th year. For many years Dr. Drysdale was a well-known figure in medical circles in London. He had been Physician to the Metropolitan Hospital, to the North London Hospital for Consumption, the Farringdon Dispensary, and to the Rescue Home. Dr. Drysdale was well-known for the interest he took in the limitation of families. He was ever outspoken on the subject, and at the time of his death was President of the Malthusian League. With him passes from the scene another of the links with the middle of last century, for it is only just short of fifty years since he took his first qualification.

ROBERT DE BRUCE TROTTER, L.R.C.P.Ed., L.F.P.S.Glas., LL.

We regret to announce the death of Dr. Robert de Bruce Trotter, of Perth, which took place at his residence on December 3rd. For the past three or four years Dr. Trotter has been ailing, but was in his usual health at the beginning of the week, and the end came rather suddenly. Born in Galloway 74 years ago, after receiving his elementary education, Dr. Trotter proceeded to the University of Glasgow, where he carried off many prizes. Subsequently he started practice in Northumberland, where he was for ten years prior to coming to Perth. In 1880 he went to the Fair City, and rapidly built up an extensive practice for himself. For twenty years he discharged the duties of Medical Officer to the General Post Office staff, Perth. In ambulance work he took a keen interest, was one of the founders of the St. Andrew's Ambulance Association in Perth, and always acted on its Committee. He was a former President of the Perthshire branch of the British Medical Association. Dr. Trotter was possessed of considerable literary talent, and, besides being the contributor of many miscellaneous articles, was the author of two well-known books, "Galloway Gossip," and a "Collection of Folklore" about Galloway.

SPECIAL ARTICLES.

MEMORANDUM ON MEDICAL INSPECTION OF SCHOOL CHILDREN.

The Board of Education have issued a Memorandum [Circular 576] on medical inspection of children in public elementary schools under section 13 of the Education (Administrative Provisions) Act, 1907, from which we extract the following:—

Scope and Purpose of the Act.—The Education Act, 1907, in so far as it concerns the medical inspection of school children, is the outcome of a steady movement of public opinion throughout the entire community. For some years past evidence has been accumulating that there exists in certain classes of the English people a somewhat high degree of physical unfitness, which calls for amelioration, and, as far as possible, for prevention. A consideration of the gravity of the need led to the conclusion that medical inspection of school children is not only reasonable, but necessary as a first practical step towards remedy, and the Board desire at the outset to emphasize that this new legislation aims not merely at a physical or anthropometric survey or at a record of defects disclosed by medical inspection, but at the physical improvement and, as a natural corollary, the mental and moral improvement of coming generations. The broad requirements of a healthy life are comparatively few and elementary, but they are essential, and should not be regarded as applicable only to the case of the rich. In point of fact, if rightly administered, the new enactment is economical in the best sense of the word. Its justification is not to be measured in terms of money, but in the decrease of sickness and incapacity among children, and in the ultimate decrease of inefficiency and poverty in after life arising from physical disabilities.

The powers and duties of a local education authority under Part III. of the Education Act, 1902, include the duty to provide for the medical inspection of children immediately before or at the time of or as soon as possible after their admission to a public elementary school, and on such other occasions as the Board of Education direct, and the power to make such arrangements as may be sanctioned by the Board of Education for attending to the health and physical condition of the children educated in public elementary schools; provided that in any exercise of powers under this section the local education authority may encourage and assist the establishment or continuance of voluntary agencies and associate with itself representatives of voluntary associations for the purpose.

Organisation.—The respective functions of the Board of Education and the Local Education Authorities are clearly defined by the Act. The duties thrown upon the Board consist in advising Local Education Authorities as to the manner in which they should carry out the provisions of the Act, and in supervising the work they are called upon to undertake; in giving such directions as may be necessary regarding the frequency and method of inspection in particular areas; and in considering and sanctioning such arrangements for attending to the health and physical condition of the children as may be submitted to them by individual Authorities. The Board will also collate the records and reports made by the Authorities and will present an annual report to Parliament. The duty of carrying out the actual inspection has necessarily been entrusted by Parliament to the Local Education Authorities, and not to the Board. Each authority must, therefore, in due course appoint such Medical Officers or additional medical assistance as may be required for the purpose. Some time must inevitably elapse before all Authorities have their arrangements in working order, but it should be carefully borne in mind that, although the work is begun gradually, the initial organisation established by each Authority should admit of such expansion as will secure the thorough and efficient administration of the Act.

After careful consideration, both of the present conditions of local sanitation and of the developments most likely to serve the economical and efficient administration of this important branch of pubilc work, the Board are of opinion that—

(*a*) In county areas the County Council, which is the Local Education Authority, should instruct their County Medical Officer, who will be responsible for smooth and effectual administration, to advise their Education Committee and to supervise the new work, its actual execution being deputed wholly or partly to suitable medical colleagues or assistants (men or women), who either will be appointed specially for the purpose under him or will be local Medical Officers of Health, and to whom groups of schools may be allocated. Where no County Medical Officer has yet been appointed under the Local Government Act, 1888, it would seem that the new duties in regard to medical inspection of children now imposed on the County Council will render it inadvisable any longer to postpone such an appointment, since in no other way will the Council be able effectually to secure adequate control, economy, and efficiency in carrying out their new work, which must obviously be guided from the central county organisation.

(*b*) In county boroughs the Town Council, which is at the same time both the Local Authority for Public Health and also the Local Education Authority, should instruct their Medical Officer of Health to advise the Education Committee and should make him responsible for the new work or for the supervision of such medical assistance as is needed to carry it out. Where appointments of school medical officers already exist, the Board do not suggest that they should be disturbed, provided always that the officers are competent and sufficient for the new duties and that the arrangements for supervision by the Medical Officer of Health are satisfactory.

(*c*) In non-county boroughs and urban districts which are Local Authorities for elementary education, the desirability of ultimately making similar arrangements, separately or in combination with contiguous districts, should be kept in view, though for the time being some variation may be requisite in accordance with local needs and circumstances.

Generally speaking, the work of inspection should be supervised by the Medical Officer of Health of the Authority which appoints the Education Committee; and when the work is obviously more than he can undertake unaided it should be entrusted to one or more medical officers working under his supervision. When it is necessary to appoint officers for the purpose of the Act, it is extremely important that persons of suitable qualifications and experience should be selected, even though they may not be called upon to give the whole of their time to these duties, and it should be noted that there are many cases in which women are likely to be specially suitable. In making such appointments preference should be given to medical men and women who (1) have had adequate training in State Medicine or hold a diploma in Public Health, (2) have had some definite experience of school hygiene, and (3) have enjoyed special opportunities for the study of diseases in children. The particular needs and circumstances of the area or group of schools concerned should receive due consideration, and great care must be taken to see that school hygiene really forms an integral and fundamental part of the public health adminstration of the district, and is not subordinated to other less important sanitary questions.

Subsidiary Agencies.—The Board are convinced that the work of medical inspection cannot be properly accomplished by medical men without assistance. The teacher, the school nurse (where such exists), and the parents or guardians of the child must heartily cooperate with the school medical officer.

Character and Degree of Medical Inspection.—From what has been said it will be clear that the fundamental principle of section 13 of the new Act is the medical examination and supervision not only of children known, or suspected, to be weakly or ailing, but of all children in the elementary schools, with a view to adapting and modifying the system of education to the needs and capacities of the child, securing the early detection of unsuspected defects, checking incipient maladies at their onset, and furnishing the facts which will guide Education Authorities in relation to physical and mental development during school life. The character and degree of medical inspection will depend on the standpoint from which the subject is viewed, the difficulty being, of course, to attain a due sense of proportion and uniformity, particularly as to fundamental points. Valuable to science though the findings of a more thorough and elaborate medical examination might be, it is the broad, simple necessities of a healthy life which must be kept in view. It cannot be doubted that a large proportion of the common diseases and physical unfitness in this country can be substantially diminished by effective public health administration, combined with the teaching of hygiene and a realisation by teachers, parents, and children of its vital importance. The spread of communicable diseases must be checked; children's heads and bodies must be kept clean; the commoner and more obvious physical defects, at least, must be relieved, remedied, or prevented; schoolrooms must be maintained in cleanly condition, and they must be properly lighted, well ventilated, and not overcrowded; the training of the mental faculties must not be divorced from physical culture and personal hygiene.

Regulations.—The Board have decided, under section 13 of the Act, that *not less than* three inspections during the school life of the child will be necessary to secure the results desired. The first inspection should take place at the time of, or as soon as possible after, admission to school; the second at or about the third year (say, the seventh year of age); and the third at or about the sixth year of school life (say, the tenth year of age). A further inspection immediately before the departure of the child into working life would be desirable where practicable, and in some areas it may be best for this to take the place of the third inspection. Certain adjustments will be necessary in working out any standard in practice, as it will at once be evident that without such adjustment the first year (1908) would be unduly burdened with the inspection of the children newly admitted and of all the children already in school.

Amelioration and Physical Improvement.—The aim of the Act is practical, and it is important that Local Education Authorities should keep in view the desirability of ultimately formulating and submitting to the Board, for their approval under section 13 (1) (*b*) of the Act, schemes for the amelioration of the evils revealed by medical inspection, including, in centres where it appears desirable, the establishment of school surgeries or clinics, such as exist in some cities of Europe, for further medical examination, or the specialised treatment of ringworm, dental caries, or diseases of the eye, the ear, or the skin. It is clear that to point out the presence of uncleanliness, defect, or disease does not absolve an authority from the consequent duty of so applying its statutory powers as to secure their amelioration, and to prevent, as far as possible, their future recurrence or development. The subject of specific medical treatment is, however, one which will require subsequent consideration in the light of the findings of medical inspection and the collateral issues raised thereby, and it is clear that, speaking generally, Local Education Authorities will be unable to formulate and submit for the Board's sanction any comprehensive scheme for the furtherance of this object until they have considered the results of their medical inspection in various directions.

This Circular is of a preliminary nature only, and concerns almost entirely the work of the new Act at its initiation.

REVIEWS OF BOOKS.

SURGICAL INSTRUMENTS IN GREEK AND ROMAN TIMES (a).

DR. MILNE is certainly to be congratulated on his book, "Surgical Instruments in Greek and Roman Times," for it enlightens us on a subject on which up to the present little or no collective work has been done. As it is, his volume forms a high testimonial to his skill and learning, and it will be a source of much pleasure to those who delight in medical archæology. The task the author has undertaken is one which might well have appalled anybody but a man of leisure, and we can only say that it is highly creditable to the industry of a practitioner that he should have been able not only to pursue all the literary research necessary to the elucidation of the shape, size, and purpose of surgical instruments among the Greeks and Romans, but also have managed to visit all the collections on the Continent and photograph the actual specimens. We doubt if there is anyone in a position adequately to criticise Dr. Milne's judgments as to the purpose for which the instruments were designed; for ourselves we may say that they strike us as sound and well thought out, and in some cases where he differs from other authorities, notably in the case of the lithotomy knife described by Celsus, he carries us with him. His explanation and design of this instrument are as convincing as they are ingenious. To those unread in medical lore it may be a surprise to learn how large a surgical armamentarium the classical nations possessed, and what a variety of operations they undertook; but perhaps the most striking thing is that Hippocrates should have been probably the most accomplished as well as the earliest of the surgeons of whom we have definite record. The photographic plates, 53 in number, which accompany the text, are beautifully executed, but it is rather a pity that Dr. Milne has not named the various instruments *in situ*. That, perhaps, is more of a lazy man's objection than a really critical point, but we feel a slight actual grievance in the fact that so scholarly a man as the author should habitually use such a solecism as "a forceps." However, the book all through is a mine of interest, and in the name of the profession we offer our warm thanks to Dr. Milne for having made available to his less fortunate brethren so fascinating a mass of information.

TRAVELS THROUGH FRANCE AND ITALY (a).

THE author being a medical man, suffering at the time from a chronic lung affection that ultimately carried him off, his letters possess a special interest for medical readers, although, in truth, he does not seem to have practised the healing art, having achieved a considerable measure of success in literature. Broken down in health, and mercilessly pursued by political enemies, he started in 1763 for Boulogne, *en route* for Montpellier, which was then apparently the most popular health resort in Southern Europe. On the way, however, he met an officer who recommended Nice, the climate whereof was "favourably spoken of with respect to diseases of the *breast.*" Passing through Montpellier on his way thither, he notes that "the air is counted salutary in catarrhous consumptions from its dryness and elasticity, but too sharp in cases of pulmonary imposthumes" (abscesses). Poor Smollett saw everything *en noir*, and bitterly complains of things in general and of French people and their ways in particular. Needless to say that the author of "Roderick Random" points his gibes with the skill of a master hand, so that his narratives are interesting as well as instructive reading. It will surprise many to find that doctors as far back as the middle of the eighteenth century talked of tubercles in the lungs and their breaking down (page 97), which, being absorbed, render the blood "acrimonious."

MEDICAL NEWS IN BRIEF

Disputed Claim.

BEFORE Judge Parry in the Manchester County Court, on December 3rd, Drs. Vipont Brown, J. Darrington Willis, and Arnold Gregory, who practise in partnership in West Gorton, sued a tram-driver named T. C. Zlatano for £3 5s. for attendance on the defendant's child. When the case was originally before the Court the defendant said the reason he had not paid the bill was because Dr. Gregory, who attended his child, had been negligent.

Dr. Gregory, who attended the child from July 9th to July 18th last, said that upon the symptoms he diagnosed the case as pneumonia, with the possibility of meningitis suggested. By means of cold baths, packs, and sponging, he succeeded in reducing the temperature. Eventually the defendant called in another doctor. Cross-examined, he denied that the child was kept in bed without any covering until July 18th on his suggestion, and that it was unscious for more than two days.

Dr. Vipont Brown said that in his opinion Dr. Gregory's treatment saved the child's life. There was not the slightest doubt that the child was suffering from inflammation of the apex of the right lung.

Dr. Reynolds agreed that the symptoms of the child's illness indicated pneumonia. The treatment given by Dr. Gregory was the only proper one under the circumstances.

Mr. Hislop submitted that the ministration of the plaintiffs had the result of leading the defendant's daughter to the point of death.

His Honour: You must not say things like that, because the evidence at present is that the effect of the treatment was to bring her back to life.

Mr. Hislop: I am suggesting he was grossly negligent.

His Honour: You might just as well say a lawyer is grossly negligent if he doesn't win his case. If that were so, 50 per cent. of the lawyers who come here would be grossly negligent.—(Laughter). If you like, you may suggest that Dr. Gregory did not use a reasonable degree of skill and care.

Dr. A. W. Martin said he found all the symptoms of meningitis. If there had been pneumonia, it was only secondary.

His Honour: Are you prepared to say that in your opinion Dr. Gregory did not treat the case with a reasonable degree of care and skill?—All I can say is that the treatment was not what I myself would have adopted. I cannot say it was wrong or improper, because each doctor has his own methods. He treated it very much as nearly all doctors do.

Mr. Hislop: In face of this I don't think I can carry the defence any further.

His Honour: No, you cannot. You, too, are only expected to treat your case with reasonable skill and care.—(Laughter.) It was a hopeless case from the first. There must, therefore, be judgment for the plaintiff for the amount claimed, with costs.

Mr. Hislop pointed out that the defendant was a poor man, and asked for time in which to pay.

His Honour: That is just like a defendant. He first won't pay the doctor, then he blackguards him, and then says, "I want his mercy and plenty of time." However, I don't suppose Dr. Gregory has any vicious feeling. He is bound to justify himself. So I shall make a small order for payment at the rate of 10s. a month.

Death under an Anæsthetic.

DR. F. J. WALDO held an inquest on Saturday on a man aged 38, who died at Guy's Hospital while under the influence of an anæsthetic. After the operation was finished, the wife was asked to come and see her husband, as another slight operation had been found necessary, but before she could start she received a telegram informing her that he had died.

John Sefton Cooper, house surgeon at Guy's Hospital, said deceased was being treated for cancer of the tongue. He consented to the final operation being performed, and Mr. Smith—a clinical assistant, though a fully qualified man—administered the anæsthetic.

Henry J. Smith said he had been a qualified medical man since June 1.

Were you appointed to give anæsthetics among your duties?—Clinical assistants are supposed to give anæsthetics when they are called upon to do so. The witness added that there were eight anæsthetists in the hospital who would deal with the worst cases. His opinion was that death was due to a sudden dilatation of the heart, caused by coughing.

Dr. Theodore Fisher, an expert pathologist, called in by the Coroner to make a post-mortem examination, said there was nothing in the organs to show that the anæsthetic had anything to do with the death.

Mr. Philip Turner (acting resident surgical officer) said that at the present time there was a large committee sitting at Guy's Hospital to inquire into the whole question of anæsthetics. He believed that surgeons, anæsthetists, and the governors were all represented on that Committee.

The Coroner said, with regard to Guy's Hospital, that this was the thirty-eighth inquiry he had held into the cause of deaths of persons who had died while under the influence of anæsthetics.

The jury returned a verdict of death from misadventure.

London Hospital.

The quarterly Court of Governors was held on December 4th, Mr. Sydney Holland presiding. The Committee reported that the Queen, President of the hospital, since the last meeting had sent a donation of £666 13s. 4d. to the general funds of the institution. In recommending for election two dental surgeons, the Committee had considered it advisable that the department should be opened on every week-day instead of only four times a week. While it was satisfactory to note that the hospital was not in debt, the cost of the upkeep was £100,000 a year, and the assured income from investments and other funds was scarcely £20,000. Without the promissory income there was a balance of £40,000 a year which had to be raised. Among the list of donations was an item of £200 which had been received from Messrs. Clarke and Robinson, the owners of Demure, who won the Cesarewitch. Before the race the owners promised that donation in the event of the horse's winning. In moving the adoption of the report, the Chairman eferred to this contribution, and hoped the laudable xample would be copied by the Jockey Club and others interested in racing. The motion was seconded by Sir F. Young, and adopted. The Chairman said next year would be their quinquennial appeal, which he trusted would be responded to in a liberal manner.

t. Bartholomew's Hospital—New Pathological Wing.

Lady Ludlow, who was accompanied by Lord Ludlow (treasurer of the hospital), laid the foundation-tone of a new pathological block, which is to be rected on a site adjoining that of the medical school, nd facing Smithfield. The ceremony was attended by most of the members of the medical and surgical staff, nd many other friends of the hospital. The Clerk of he hospital, on behalf of the governors, read an address to Lady Ludlow. The address stated that the uilding was to be devoted to investigations in pathoogy and in pharmacology. The discoveries thus made nd the observations recorded would be of benefit to atients, whether within the hospital or without, hroughout the world. The address also alluded to he administration of Lord Ludlow, as treasurer, hich, it pointed out, had been of the greatest benefit St. Bartholomew's, while his period of office would always commemorated by the many new buildings ected. The new building is to be erected at a cost £30,000, and a special appeal is to be made for at amount.

ommittee of the London Ambulance Service.

The Committee appointed by the Secretary of State or the Home Department to inquire into the question the ambulance provision for cases of accident and udden illness occurring in streets and public places the Metropolis met at the Home Office on December 6th, Sir Kenelm Digby (chairman), presiding. Evidence was given by Mr. Samuel Osborn, F.R.C.S., chief surgeon of the Metropolitan Corps of the St. John Ambulance Brigade, the Hon. Sydney Holland, chairman of the London, Poplar, and Tilbury Hospitals, and deputy-chairman of the London and India Docks Company, Mr. F. W. Higgs, M.B., B.S., acting resident medical officer, St. George's Hospital, and by Dr. Henri Nachtel, of Paris. Any communications on the subject of the inquiry may be addressed to the Secretary, Mr. A. L. Dixon, Home Office, Whitehall, S.W.

Notification of Births Act in Dublin.

At the last meeting of the Corporation of Dublin, the Lord Mayor moved the adoption of the Notification of Births Act. Dr. McWalter opposed the adoption, and suggested that the question be deferred for twelve months, as it would entail extra expense on the Sanitary Department and was of doubtful utility for the conditions prevailing in Dublin, where excessive infantile mortality was mostly due to mere poverty. The consideration of the question was eventually deferred for one year.

Public Medical Service in Birmingham.

Another meeting of Birmingham doctors was held last week at the Medical Institute for the purpose of considering the proposals for the establishment of a public medical service. After prolonged discussion the meeting decided that it would not be advisable to establish the proposed service in Birmingham, the voting being 27 for and 60 against.

PASS LISTS.

University of London.

The following candidates have passed the M.B., B.S. Examination:—

Honours.—Richard H. C. Gompertz, B.Sc. (*a*, *d*, University Medal), T. S. Higgins, B.Sc. (*b*), James L. Lawry (*d*), Elizth. H. Lepper (*b*), Alfred Richardson (*a*), Clare O. Stallybrass (*c*, *d*), Leonard H. Wootton, B.Sc. (*d*), Andrew J. M. Wright (*a*, *d*).

(*a*) Distinguished in Medicine.
(*b*) Distinguished in Pathology.
(*c*) Distinguished in Forensic Medicine and Hygiene.
(*d*) Distinguished in Surgery.

Pass.—Samuel H. C. Air, Edgar Alban, Ardeshir P. Bacha, Laurence Ball, Frederick J. F. Barrington, Walter R. Bristow, Thomas E. A. Carr, Herbert S. Chate, B.Sc., Meyer Cohen, Walter F. Corfield, Ernest M. Cowell, Davis W. Daniels, Eleanor Davies-Colley, Eric J. De Verteuil, Carel C. A. De Villiers, Reginald L. E. Downer, Kenneth E. Eckenstein, Marmaduke Fawkes, Charles H. Fielding, Vera Foley, Arthur Fothergill, Ernest C. Hadley, John Hadwen, B.Sc., Eric H. R. Harries, Claud S. van R. Harwood, Herbert Hawker, Geo. M. W. Hodges, Edward H. Hugo, Douglas W. Hume, John P. Johnson, Henry T. Jones, Edgar H. Kettle, Clement Lovell, Eleanor Lowry, Emily M. S. Mecredy, Humphrey Nockolds, Evelyn H. B. Oram, Basil T. Parsons-Smith, Walter Patey, John G. Phillips, Jeffrey Ramsay, Samuel S. Rendall, Russell J. Reynolds, William Scarisbrick, B.Sc., Shantaram R. Shirgaokar, Marie Simpson, Eliza M. Smith, Horace E. R. Stephens, Robert Y. Stones, Arthur A. Straton, Reginald S. Townsend, Alfred G. Tresidder, Harold S. Vivian, Cuthbert G. Welch, Ruth H. Western, Henry Whitehead, Harold W. Wilson, John Black F. Wilson.

The following have passed in one of the two groups of subjects:—

M.B., B.S. Examination.—Group I.—Charles A. Basker, Janet M. Fishe, Susie E. Hill, Laura G. Powell, Mona D. Roberts, Frederick G. Sergeant, Thomas G. S. Smith, John J. Suckling, Cuthbert F. Walker.

Group II.—George N. Bartlett, Stanley J. A. Beale, Alfred Bernstein, John W. Bride, Herbert R. Davies, Clara Eglington, Frederick P. Fisher, Charles T. Hawkins, Maurice J. Holgate, John B. Martin, Alexander M. Pollard, Ethelbert W. Squire, Hugh Stott, Arthur L. Yates.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for **The Medical Press and Circular.**

RECENT MEDICAL LITERATURE.

Para-Nephritic Abscess.—Halsey reports a case of this rare affection, the patient, a man of 22, contracted a gonorrhœa eight weeks before admission. He was also under treatment for syphilis, which he had got about a year previously. Four weeks before admission pain began in his back, at first on the left side and later on, as the pain became more severe, spreading to the right side also. In the four weeks he had lost seven pounds weight. His inguinal and femoral glands were very much enlarged, those on the left side were exquisitely tender. There was no rigidity of the recti muscles, but deep pressure in the left hypochondrium caused pain. His temperature was 104, his pulse 116, urine showed no casts, no albumin, no indican, cystoscopic examination of the bladder revealed nothing abnormal. Ten days after admission to hospital he developed spasm of the left psoas muscle, which prevented him completely extending the left thigh, and soon after a slight bulging appeared in the left lumbar region, just below the ribs, and it was thought that a retro-peritoneal abscess was present. By an incision at the outer edge of the erector spinæ muscle a large amount of pus was evacuated, the kidney could be felt above the abscess, which was behind the peritoneum and external to the psoas muscle, and evidently external to the peritoneum. The patient's recovery was uneventful. It is interesting to note what was the probable course of the infection in this case, while the ureter and bladder were free from infection, the lymph glands were undoubtedly the path by which the infection travelled to the deep lumbar glands, those lying upon the psoas muscle being obviously the most vulnerable. Enlarged because of the syphilitic infection, the superadded gonorrhœal infection was too great, and an abscess formed; in reality this might be called a bubo inferior to the left kidney. The complete absence of any kidney irritation is also worthy of note. G.

Treatment of Tumours of the Central Nervous System.—Oppenheim (*Berlin Monograph*, 1907) says the prognosis of brain tumours is far more unfavourable than the prognosis of tumours of the spinal cord. In the former cases, the author noted only 11 per cent. of recoveries, and over 50 per cent. of failures, which must be designated as the results of operation. The surgical treatment of tumours of the spinal cord had resulted in permanent cures in about 50 per cent. of the cases so treated. The prognosis in the author's cases was made considerably worse by the fact that a proportion of 44 per cent. of his brain tumours belonged to the group of tumours of the posterior cranial fossa, and the prognosis in such cases is always unfavourable. From his statistics it appears that in only about one case out of ten carefully selected cases of brain tumour is operation likely to result in permanent and complete cure. The author believes that in the near future the surgical treatment of tumours of the spinal cord will be employed far more frequently, and that in consequence the prognosis will be greatly improved. Exploratory laminectomy should be done far oftener than it is, as it affords the only true means of recognising operable tumours in many cases where a positive diagnosis is prevented by the symptoms being very obscure. In such cases it is nearly always necessary to incise the dura, and the operator should never hesitate to do this,—indeed in most cases it is clearly indicated. The author believes that the operation of laminectomy is attended with comparatively no danger, and from observations made on his own cases at a considerable time after such operations, it seems that the patient suffers little or no weakness or inconvenience from the removal of several of his laminæ. G.

Frequency of Micturition in Women.—*The Hospital*, July). In women of middle age frequency of micturition is by no means uncommon. Inquiries should always be made in such cases if the frequency is by night as well as by day. In some cases of prolapsed uterus the frequency is markedly present in the day time, but almost absent at night when the patient is lying down. All such cases of frequency come under one or other of the following headings:—(1) Those cases which depend on some change in the urine; (2) those cases which depend on some condition outside the bladder; and (3) those cases which depend on some actual disease of the urinary tract from the kidney downwards. The most common cases are those which depend on some change in the urine, such as excess of urates, or excess of phosphates, and hyperacidity. In such cases diet, digestion, and a sedentary occupation are often responsible for the condition, and when they are remedied relief from the frequency will follow. The common lesions outside the bladder are tumours on the fundus of the bladder, early pregnancy, prolapse of the uterus, unilateral pelvic cellulitis, and pelvio-peritonitic adhesions. For such conditions citrate of potassium, hyocyamus and chloroform will often be of use. The third group of cases may require the cystoscope for their diagnosis, although even here the cystitis can be discovered by careful urinary examination. It is well to bear in mind that mild cases do not call for lavage of the bladder. Besides prolapses, vaginal discharges or dirty catheters may cause cystitis. Calculus, tuberculous ulceration, malignant growths, papillomata and varices at the neck of the bladder are rare, and require the cystoscope for their differential diagnosis. Stone in the kidney, renal growths, Bright's disease, diabetes, movable kidney, pyelitis, pyonephrosis, and tuberculous disease of the kidney may all cause frequency, and must be borne in mind; repeated and careful examinations of the urine and kidneys will in most cases enable a diagnosis to be formed. G.

Case of So-called Traumatic Asphyxia.—Beatson (*Glasgow Med. Journ.*, Nov., 1907) reports a case of traumatic asphyxia in a man æt. 24. He had been crushed antero-posteriorly by a pit cage, and his shoulders driven downwards and forwards into the abdomen and pelvis. There was intense congestion of the head and neck, almost petechial in character, but not affected by pressure. There was considerable œdema around the eyes and mouth. Sub-conjunctival hæmorrhage was considerable, and there was a large sub-lingual hæmatoma. There was also a probability of some hæmorrhage into the orbit, as there was some ptosis. There was no fracture. In three days the congestion and discolouration began to fade, and by the eighth day this was only present in the forehead, where it now yielded to digital pressure. There was discolouration around the eyes and nose, as in ecchymosis. In a short time all the discolouration had disappeared. S.

Movable Kidney from a Surgical Standpoint.—Billington (*Brit. Med. Journ.*, Nov. 30th, 1907) describes an operation for movable kidney which he has employed with success 70 times. The skin incision is parallel to the erector spinæ, and starts a little above and just behind the tip of the twelfth rib. The kidney is brought out into the loin. All adhesions, which are often of great density, should be cut with a scissors curved on the flat, so as to leave the kidney attached by its pedicle only. A triangular piece of kidney capsule is raised from the kidney. The apex of this flap of capsule is taken from the upper pole of the kidney. The base is left attached, and extends from the hilum to the centre of the convex border of the kidney. Two stout strands of silkworm gut are now passed beneath the unraised capsule in the way described by Goelet. The free ends of the silkworm gut sutures and the apex of the loose piece of capsule are clamped with a pressure forceps, and the kidney replaced in the loin. The upper part of the anterior surface of the quadratus lumborum is cleared, so that the kidney, when fixed in position, shall be against the muscle itself. The final fixation is now proceeded with. A pair of closed Spencer Wells forceps is forced through the muscles of the eleventh intercostal space immediately behind the tip of the twelfth rib, and made to seize the apex of the triangular piece of loose capsule. The kidney is pushed up from below until the base of the denuded area is on a level with the lower border of the twelfth rib. The loose strip of capsule is then drawn taut, and fixed by means of fine silk to its own base. In this way the kidney is suspended by a loop of its own capsule, which passes completely round the rib. Both ends of the two silkworm gut stitches already mentioned are made to pass through the ligamentum arcuatum externum, and through the skin about one inch above the skin incision. They are tightened and tied over a gauze pad. The skin stitches are removed at the end of a week, but the supporting stitches are left in for three weeks. The patient is kept in bed for a month, and then provided with a light belt or an elastic webbing bandage applied in the form of a spica which is to be worn for six months. S.

A Simple Operation for Uncomplicated Oblique Inguinal Hernia.—Chiene (*Brit. Med. Journ.*, 16th November, 1907) describes an easy and quickly performed method of operative procedure for the above condition. It can readily be done under a local anæsthetic. The author has employed it in 16 cases during the last 18 months with very satisfactory results. The skin incision is made half an inch above and parallel to the middle third of Poupart's ligament, the centre of which corresponds to the position of the internal abdominal ring. The external oblique is divided in the direction of its fibres, and the cremasteric muscle fibres are divided in the same direction. The internal oblique and tranversalis are retracted upwards and outwards, and the tranversalis fascia divided in the same direction as the external oblique. The neck of the sac is thus exposed at the internal ring. It is freed from the cord, opened and divided. The neck is ligatured and fixed to the under surface of the abdominal wall above and external to the internal abdominal ring, the rest of the freed portion being cut off. The split fibres of the external oblique are then sutured by the over-lapping method. In some cases the divided cremasteric fibres require a stitch to bring them together. The internal oblique and tranversalis therefore are left untouched, and the sac, with the exception of a small portion at the internal ring, is left *in situ*. S.

The After-History of Two Cases of Inter-Scapulo-Thoracic Amputation for Sarcoma.—Thomson (*Edinburgh Med. Journ.*, November, 1907) details two cases showing the sad contrast of the after-history in sarcoma of the shoulder to the brilliant immediate results that follow the extensive operation. Case 1. A miner, æt. 20, six months before operation was struck on the left shoulder while working in a pit. On admission to hospital there was a prominent swelling in the deltoid region, and marked wasting of the scapular muscles and the biceps. The movements of the shoulder joint were limited, and there was some grating of the articular surfaces. The limb and shoulder girdle were removed on August 8th, 1901. On dissection the tumour was found to have taken origin from the periosteum of the upper end of the humerus. It had involved the shoulder joint, which was full of blood, and had spread to the substance of the scapular muscles, especially the infraspinatus and teres minor. The growth was a mixed celled sarcoma. The patient made an excellent recovery, and remained perfectly well for the greater part of two years. Soon after that the patient complained of pain in the left thigh and leg, and a tumour rapidly formed in Scarpa's triangle. On admission to hospital the disease had already made such rapid progress that radical operation was out of the question. The patient died on May 31st, 1904, a little less than three years from the time the disease first appeared in the shoulder. Case 2. A girl, æt. 14 years, had suffered from pain in the left shoulder for three months. About a month before admission to hospital on February 27th, 1907, a swelling had been noticed, which had increased rapidly. On 3rd March, 1907, the operation was carried out according to Kocher's description, except that the inner half of the clavicle was evulsed from the epiphyseal junction. The tumour was found to be a chondro-sarcoma opening from the upper end of the humerus. For two or three days after the operation the patient was bright and well. Then she developed a troublesome cough, and died on March 27th with malignant disease of the pleura. S.

General Miliary Tuberculosis Diagnosed by Choroidal Tubercle.—Cargill and Mayor (*Trans. Ophthal. Soc.*, 1906) record an interesting case in which the finding of tubercle of the choroid in one eye and a neuroretinitis in the other solved the diagnosis between typhoid fever and general miliary tuberculosis. For six weeks before admission the patient, æt. 21, had been unwell, and for a month had been confined to bed with headache, feverishness and constipation. On admission (Dec. 11th, 1905) he had the "typhoid appearance," temperature 100.6°, pulse 100, respirations 24. No physical signs in lungs, heart, or abdominal organs. No spots. Widal's reaction was negative. Opsonic index for t.b. was 1. No tubercle bacilli were found in the sputum or blood. After admission the temperature varied from 98° to 103°. On December 18th, 1905, the eyes were examined ophthalmoscopically, and choroidal tubercles were seen in one eye and neuroretinitis in the other. Three days before death, on February 20th, 1906, tubercle bacilli were found in small numbers in the sputum for the first time. An autopsy revealed general miliary tuberculosis, the tubercles being found in the meninges along the arteries, over the surface of the liver, pancreas, kidneys, and suprarenals. The lungs were thickly studded with large and small foci. Although general tuberculosis was the most likely diagnosis in this case, the ophthalmoscope afforded nine weeks before death the only physical signs which gave any certainty. The detection of choroidal tubercle is, of course, most helpful in diagnosing the general condition, but it is evidently rare, as Osler says he has "never known a diagnosis made on their presence alone." M.

Children's Sanatorium.

To aid the Children's Sanatorium for the Treatment of Consumption, Holt, Norfolk, an exhibition of pictures and calendars, organised by Miss K. M. Wyatt, whose father is hon. secretary to the institution, and a number of friends, was held on Saturday in the rooms of the Royal Female School of Art, Queen Square. Pending the collection of funds with which to provide permanent accommodation, temporary buildings have been erected at Holt, and a number of cases have already been treated and discharged as "apparently cured." These temporary premises are large enough to receive 15 children, but owing to lack of funds, only 11 cases at a time have been dealt with. To erect the permanent building at present contemplated about £5,000 is required—the site has already been purchased—and of this sum £1,000 is in hand. The Holt Sanatorium was the first, and until recently the only, establishment for the treatment of consumptive children. The exhibitors on Saturday included Mary Countess of Ilchester, Lady Maxwell-Lyte, Miss Gloagh, Miss E. R. Stone, Miss Woodward, and Miss K. M. Wyatt. All the work shown, which included some embroidered fancy articles by Miss Thomas, was for sale, and a sum of over £40 was realised.

Owing to the prevalence of measles, all the infants' schools in Chester have been closed.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTICEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

NESCIS.—We have frequently suggested that medical men should adopt the practice of asking for half the confinement fee at the time the engagement is booked. It is not unusual, and is perfectly legitimate. The contract, of course, is equally binding on both sides in such an event, but the obligation is thus assured. The circumstances are annoying, but if you put the patient in the County Court you might quite well lose the case, as you were absent when wanted, and another practitioner was so obviously needed.

FACIES.—Freckles may be treated—if necessary—by drugs that cause exfoliation of the epidermis. A good application is a 1 per cent. solution of perchloride of mercury in alcohol; it should be continued from day to day till the required irritation is produced; 50 per cent. resorcin in zinc paste (Unna) is also useful, but would require the patient to remain indoors.

A DISCLAIMER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was lately consulted about his eyes by the editor of a provincial newspaper. On his return home, being evidently unacquainted with the rules of the medical profession, he inserted in his paper a paragraph praising my skill as an oculist. I wish to say that the paragraph in question was written and inserted entirely without my knowledge, consent or approbation.

Yours faithfully,
SEAGHAN P. MACENRI.
(JOHN P. HENRY.)

32, Lower Leeson Street, Dublin,
December 8th, 1907.

AQUA DEST.—The name Still's disease is applied to a condition allied to the rheumatoid anthritis (so-called) of young people. Still's disease is a disease of children, and is accompanied by enlargement of the spleen and lymphatic glands.

DR. E. C. T. (Hampstead).—We greatly regret that the insertion of a news paragraph should have given colour to any suspicion that we approve of the treatment in question. We have dealt with it several times in the MEDICAL PRESS AND CIRCULAR, and thought our readers were well acquainted with our views. Although there are unfortunately well meaning philanthropists connected with it, there is an "inventor" in the background who is frankly interested in the sale of the remedy.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 11TH.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—5.30 p.m.: Paper:—Dr. Edgecombe (Harrogate): Blood Pressure in Spa Practice.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. T. P. Legg: Clinique. (Surgical.) 5.15 p.m.: Lecture: Dr. L. Guthrie: Precocious Development.

THURSDAY, DECEMBER 12TH.

ROYAL SOCIETY OF MEDICINE (OBSTETRICAL AND GYNÆCOLOGICAL SECTION) (20 Hanover Square, W.).—7.45 p.m.: Specimens will be shown by Dr. C. H. Roberts, Dr. P. Horrocks, Dr. J. Oliver, Dr. H. T. Hicks, and Dr. Lewers. Paper:—Dr. W. E. Fothergill: The Supports of the Pelvic Viscera, a Review of some Recent Contributions to Pelvic Anatomy with a Clinical Introduction.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—Papers:—Mr. L. Paton: The Diagnosis and Treatment of Some Forms of Simple Conjunctivitis.—Mr. W. F. Fedden: Congenital Talipes.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Card Cases: Mr. R. J. Smyth, Mr. S. Mayou, etc. 8.30 p.m.: Papers:—Mr. S. Snell and Mr. E. Nettleship.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4 30 p.m.: Lecture:—Dr. A. G. Auld: Varieties of Cough, their Diagnosis and Treatment.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Fungous Diseases of the Hair: III., Favus; IV., Leptothrix.

HOSPITAL FOR SICK CHILDREN (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. Fairbank: Congenital Dislocation of the Hip and its Treatment.

FRIDAY, DECEMBER 13TH.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (20 Hanover Square, W.).—8.30 p.m.: Exhibition of Cases by Dr. E. Reid, Prof. W. Osler, Mr. T. H. Openshaw, Dr. F. P. Weber, Dr. W. E. Wynter, Dr. W. Pasteur, and Dr. F. J. Poynton. The patients will be in attendance at 8 p.m.

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m.: Shaw Lecture:—Prof. T. Oliver: Industrial Poisons—Lead and Phosphorus, with Special Reference to the Manufacture of Lucifer Matches.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.).—5 p.m.: Special Meeting. Discussion on Inherited Syphilis (opened by Mr. C. Lucas). Followed by Dr. Adamson, Dr. L. Guthrie, Dr. G. Carpenter, Mr. G. Pernet, Mr. S. Stephenson, Mr. A. H. Tubby, and others.

TUESDAY, DECEMBER 17TH.

THE MEDICO-LEGAL SOCIETY.—THE ROYAL ASIATIC SOCIETY (22 Albemarle Street, W.).—8.15 p.m.: President, the Hon. Mr. Justice Walton: 1. Narration of Cases and Exhibits of Medico-Legal Interest; 2. "The Radical Cure—Certification of Inebriates": T. Claye Shaw, M.D.

ROYAL SOCIETY OF MEDICINE (THERAPEUTICAL AND PHARMACOLOGICAL SECTION) (Apothecaries' Hall, Blackfriars, E.C.).—4.30 p.m.: Dr. James McKenzie: The Action of Digitalis on the Human Heart.—Dr. William Soper: Reminiscences of an Apprentice Fifty Years Ago.

Appointments.

CROSSFIELD, H. V., M.B., C.M.Glasg., Clinical Assistant to the Chelsea Hospital for Women.

GREEN, PHILIP, M.D., M.R.C.S., L.R.C.P., Clinical Assistant to the Chelsea Hospital for Women.

HENRY, F., M.B., Ch.B.Glasg., Medical Superintendent of the Highfield Infirmary, Liverpool.

LEGGETT, WILLIAM, M.B., Ch.B., B.A.O.Dub., Senior Assistant Physician at Montrose Royal Asylum.

MURRAY, JOHN, M.B., B.Ch.Dub., F.R.C.S.Eng., Surgeon to the Middlesex Hospital.

POLLARD, ARTHUR HAIG, L.R.C.P., M.R.C.S., House Physician to the Cheltenham General Hospital.

STUART, EFFIE GORDON, M.B.Edin., Assistant Resident Medical Officer at the Sheffield Union Infirmary.

TAYLOR, GORDON, M.B., M.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the Middlesex Hospital.

Vacancies.

Birmingham City Asylum.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Suffolk District Asylum, Melton.—Second Assistant Medical Officer. Salary, £160 per annum, with board, furnished apartments, attendance, and laundry. Applications to the Medical Superintendent.

Bristol General Hospital.—Senior House Surgeon. Salary, £120 per annum, with board, residence, etc. Applications to the Secretary, W. Thwaites.

Stockport County Borough.—Medical Officer of Health. Salary, £450 per annum. Applications to Robert Hyde, Town Clerk, Town Clerk's Office, Stockport.

Leeds City.—Assistant Medical Officer of Health and Chief Inspector of Nuisances. Salary, £300 per annum. Applications to Robert E. Fox, Town Clerk, Leeds.

Great Northern Central Hospital, Holloway Road, N.—Pathologist and Curator. Salary, £100 per annum. Applications to L. H. Glenton-Kerr, Secretary. (See Advert.)

Births.

CUTCLIFFE.—On Dec. 6th, at Court Green, North Tawton, Devon, the wife of Montagu Cutcliffe, L.R.C.P., M.R.C.S., of a daughter.

KINGDON.—On Dec. 5th, at Nelson Street, King's Lynn, the wife of J. Renorden Kingdon, M.R.C.S., L.R.C.P., of a daughter.

SAWYER.—On Dec. 5th, at 14, Farquhar Road, Edgbaston, Birmingham, the wife of James E. H. Sawyer, M.A., M.D., of a daughter.

Marriages.

HILL—BARKER.—On Dec. 5th, at the Parish Church of Llanfor, Merioneth, Charles Alexander Hill, M.A., M.B., of 13, Rodney Street, Liverpool, to Ethel Constance, third daughter of the late Richard Barker, of Huyton.

VERLEY—NORFOLK.—On Nov. 16th, at the Parish Church, Halfway Tree, Jamaica, Reginald Charles Verley, M.B., Ch.B., M.R.C.S., L.R.C.P., B.Sc.(Edin.), son of the late James L. Verley, of Jamaica, to Helen, fourth daughter of the late Robert Norfolk, J.P.

Deaths.

DRYSDALE.—On Dec. 2nd, at 28, Carson Road, West Dulwich, Charles Robert Drysdale, M.D., M.R.C.P., F.R.C.S. Consulting Physician to the Metropolitan Hospital, aged 78.

GRAHAM.—On Dec. 5th, at 14, Old Cavendish Street, London, George Herbert Graham, M.D., late of Storrington.

JEAFFRESON.—On Dec. 1st, at Rouxville, Orange River Colony, South Africa, Alfred Ernest Jeaffreson, M.B., B.C.Cambridge, M.R.C.S., L.R.C.P.London, formerly Assistant Physician of Bridewell Royal Hospital.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, DEC. 18, 1907. No. 25.

NOTES AND COMMENTS.

The "Standard" and Medical Butchery.

AN advertisement which appeared in the *Standard* has been sent to us. It is headed, "Appendicitis and Medical Butchery," and proceeds on this wise :—"Why be slain by costly operations when a certain cure can be obtained by natural means? A few years ago no such disease could be found in the medical vocabulary, and there is a VERY GREAT USE FOR THE APPENDIX the ignorance of which is a disgrace to the medical profession." After this opening we are not surprised to find a lot of mystic bunkum about "magnetic auras," "vital force," "nervous breakdown," and so on, and a statement that "all this can be stopped by scientific magnetic force from a gifted healer." This endowed individual is "Professor" W. H. Edwards, "who has been publicly tested in every variety of disease," "and who positively undertakes to relieve every kind of internal inflammation, often mis-called 'appendicitis,' without operations of the surgeon's knife." After reflection, we have little hesitation in saying that we consider this advertisement the most offensive concoction that we remember to have read, and to label it as a disgrace to the *Standard*, or any other paper claiming respectability. Under the old management it would have been impossible for such an impudent libel on the medical profession or any other body of men to find its way into the advertisement columns of the *Standard*, but apparently times have changed, and, with them, manners.

Quantum Mutatus.

WITH "Professor" Edwards we are not much concerned. Gentlemen of his kidney are sufficiently numerous, and more than sufficiently offensive to medical practitioners who abide by a code of honour and rules of decency. But that a responsible journal of the type of the *Standard* can so far forget what is due to any recognised profession as to print in large letters such an abominable insult as "Appendicitis and Medical Butchery" is a more serious matter. It shows, we think, a very rapid and abysmal fall from what was till recently considered becoming and decent, and we would advise medical men who read journals which degrade themselves in this way to write to the editors by way of protest. In the absence of decided action or expression of feeling these insults have gone from bad to worse, till "Medical Butchery," in speaking of ordinary surgical proceedings, is not considered too outrageous for a journal appealing to the better educated classes to publish in the ordinary way.

The "Daily News" and Student Disturbances.

PAPERS hostile to medicine and national science, such as the *Daily News* and the *Star*, had another innings last week through the renewed "Brown Dog" disturbances. The *Daily News* is frankly delighted. "We welcome these demonstrations," it says, "because they are favourable to the anti-vivisectionist cause." As in the same article it is asserted that some of the demonstrators were drunk—a suggestion we have not seen put forward elsewhere—the joy that animates a nominally temperance paper such as the *Daily News* would be hard to understand, if we did not realise that no weapon is too tarnished and no blow too foul if thereby medical men and science are to be hit. Student rows are common in all University towns, whether in Scotland, Ireland, Wales, Oxford, or Cambridge, and people accustomed to the presence of students recognise them to be irresponsible creatures, who are not always wise, not always rational, and, alas! not always possessed of discriminating taste. The police in University towns, as a rule, understand student-nature, and practice the art of restraint with good sense and good temper; the London police have so little experience of student manifestations that they regard them much as the Russian police do demonstrations at the universities in that bureaucratic country. It is utterly irrational, of course, for students at the same time to protest against an offensive monument and to turn it into a joke; the phenomenon can only be explained on the well-known principle of "turning to mirth all things on earth, as only boyhood can."

Philosophy of Strikes.

BUT if a mob of strikers, labouring under a sense of injustice, break the windows of Government offices or smash the railings in Hyde Park, the statesman, while condemning the excesses, seeks for the cause of the trouble, and endeavours to adjust it. Breaking windows, smashing railings, and parading effigies of dogs, are stupid and reprehensible methods, but they generally indicate a grievance, and they do not necessarily indicate the offenders to be possessed of a larger dose of original sin than their fellows who have not a grievance. There are many gentlemen of the highest respectability holding exalted positions in the State who, in their younger days, have been guilty of blatant excesses. Every man of middle-age can point out a dozen well within his own knowledge. So that to found any argument on the present regrettable street-rows is not only unfair but plainly the outcome of spite looking for a reason to justify its existence. This is all the more evident when it is remembered that the very papers that are now using the incidents under notice for their own purposes, were a few months ago doing all they could to mollify the disgust excited in the public mind by the unwomanly tactics of the "Suffragettes," and only retreated from that attitude when they found they had burned their fingers and that the demonstrations of these Amazons were directed personally at the leaders of their own political party. We do not remember these journals welcoming the demonstrations as being fatal to the cause of women's suffrage, or as showing what sort of order in the country would be the probable result of the success of the movement.

Snobbery and Abuse.

But the vapourings of the *Daily News* are outdone by the lucubrations of the *Star*. This journal is, perhaps, the most persistent reviler of medicine, and what it is pleased to call the "medical priesthood," that we have to contend with. As it is very ably edited and has a large circulation among the working-classes, the injury it does to the poor in the way of sowing distrust of medical advice is doubtless very great. Considering that its advertisement columns are filled with the most offensive announcements of quack medicines, and its revenue is therefore largely dependent on the money extracted from the poor by their sale, any pretence of serving the public interest by denouncing medical methods is calculated to strike an observer as the most unctuous hypocrisy. The student disturbances are a god-send to the *Star*. It begins a leader on them by sympathising with the police, a force which it usually delights in denouncing, and which a non-medical witness described in this particular instance as behaving "like a lot of savages." It then toadies to the older universities by congratulating them on their refusal to join the "medical larrikins" in "the riot," and proceeds sarcastically to inquire "at what stage in his evolution does the medical hooligan become the humane scientist?" Finally, it winds up its article with a quotation, adapted from something Robert Louis Stevenson wrote about the art students of Paris, and applies it "to the cads of medicine" Surely gutter journalism, under the transparent guise of righteous indignation, here reaches its nadir.

"Un-English, libellous, and provocative."

For every reason we are glad to think that this painful chapter of incidents is likely soon to be closed. A member of the Battersea Borough Council, Mr. Runeckles, has given notice that he will move at the next meeting of that body that, "as a matter of good sense and good taste, the un-English, libellous, and provocative inscription of 'Little Brown Dog Memorial' be removed." We sincerely hope that the Borough Council of Battersea will accept the motion. As we have said before, the inscription is not only calculated but is obviously designed to stir up ill-feeling, and on every ground such a cause of offence should be removed. Mr. Runeckles is taking a dignified and statesmanlike step, and we trust the Council will dismiss from their minds all prejudice and prepossession and accept the motion.

LEADING ARTICLE.

DABBLING WITH HUMAN AILMENTS.

The coroners of the United Kingdom have undoubtedly a great power in their hands as regards the suppression of the evils of patent medicines and unqualified medical practice. To their honour be it said that the matter has engaged their attention both collectively in their society discussions, and individually in many conspicuous instances. For the full position of this tragedy is to be found in the dead bodies of the patent medicine vendors' victims who are thus brought before the public as grim evidence of the cupidity of their fellow-men. The single article of so-called teething powders is answerable every year for the deaths of a great number of infants. Yet the trade goes merrily on, and the proprietors of these poisonous and scientifically worthless nostrums amass large sums of money out of the credulity of the poorer classes. Then there is the noxious class known as herbalists, whose names are not infrequently connected with illegal operations. Two recent cases of public censure of such persons by coroners for quackery may be cited. In the first, Mr. S. Brighouse, County Coroner, held an inquest upon the infant son of a collier named Cawley, living in Ashton-in-Makerfield. The child, previously healthy, was taken ill when about ten months old. The mother began treatment with a "Fenning's tooth powder," an unknown quantity, and a dose of castor oil. Next morning the unfortunate child appeared a little better and she gave another dose of castor oil, but the day after she went to Mr. Hill, a herbalist, of Ashton, and obtained a bottle of mixture and a powder. Next day the child died before the arrival of a medical man, who was not summoned until that stage of the proceedings. In evidence it was shown that Mrs. Hill examined the child, and sixpence was paid for advice, medicine, and powders. As a matter of fact, the child died from bronchial pneumonia; no attempt had been made to take the child's temperature, so that the data for a proper diagnosis were defective. It appeared that the Hills had dosed the unhappy infant with syrup of rhubarb and antifebrin. With regard to the latter drug, it is not necessary to remind medical readers of the risks attending the use of so powerful a drug. Of the many deaths that have followed its use some at least have been amongst young persons, and its administration to infants requires the exercise of the highest and most responsible medical skill available. The fact that ignorant persons can openly avow in a public Court that they have prescribed antifebrin shows the impotence of the Medical Acts to protect the safety of our countrymen against the machinations of unqualified medical practice. The woman herbalist had the brazen audacity to state she had used antifebrin for the past twelve years. In accordance with the wish of the jury, Mr. Coroner Brighouse gave this precious pair a sound rating for "dabbling" with human ailments about which they knew nothing. There the matter ends, but surely the police, had they a mind to it, could prosecute this Hill and his wife for obtaining money under false pretences. The attention of Parliament might well be called to this incident by any Member who is sufficiently interested in the safety of the community, especially of its rising generation. The second case to which we would refer briefly was divulged at Brighton on October 10th. The Coroner, Mr. J. E. Bush, held an enquiry into the death of a young woman who had died shortly after being discharged from the Sussex County Hospital, where she had been under treatment for leukæmia. Her case was regarded as hopeless, and her friends called in a local herbalist of the name of Stokes. This man visited the poor girl at home, and gave her medicine "for the kidneys, liver, and nerves," in spite of which treatment he admitted having been surprised at her sudden collapse and death. He claimed, however, that he had kept her alive for eighteen days. This man had the impudence to boast he had been "practising" for over fifty years, and had cured cases given up by doctors, and even doctors themselves. The

Coroner wound up with the usual formal censure of the herbalist, at the wish of the jury. Such practices, it is needless to remark, will need more drastic handling than the mere delivery of a public remonstrance. "Hard words break no bones" is essentially a motto for quacks. It is to be hoped that the movement recently set on foot by the General Medical Council will result in some short and sharp legislation to rid society of such cruel harpies and parasites as herbalists and other quacks of the same kidney.

CURRENT TOPICS.

Suggested Royal Commission on Scarlet Fever.

It may be still remembered that three years ago The Medical Press and Circular took up strongly the position that a Royal Commission, or other authoritative inquiring body, should be appointed to investigate the relation of isolation hospitals to the spread of scarlet fever. By means of papers contributed by medical men having special knowledge of the position, and by editorials, the matter was placed before the public, and although some support was received, the matter, on the whole, was not warmly accepted. We realised that the isolation hospital was such a convenience in many ways that, as regards scarlet fever, any steps that seemed to infringe its prerogative would be certain to meet with opposition; but we held then, and hold as strongly to-day, that the problem is a great and puzzling one calling for a large and independent investigation, considering the magnitude of the sums invested in maintaining scarlet fever patients and the poverty of the results achieved. We have returned to the subject over and over again, but the fruit, though long in ripening, has yet to be gathered. That step, however, is appreciably nearer. On December 5th, Professor W. R. Smith submitted a motion to the Metropolitan Asylums Board to the effect that in view of the continued prevalence of scarlet fever, notwithstanding the extensive isolation accommodation which has been provided, the Local Government Board be asked to cause an inquiry to be instituted into the cause of the disease, and whether any, and if so, what, further means can be adopted for its prevention. Professor Smith said that medical science had not yet discovered the cause of the disease, and by an inquiry the burden on the ratepayers might be reduced. Personally, he thought the matter ought to be submitted to a Royal Commission. That motion was adopted unanimously.

The Extinction of the Eskimos.

One of the ironies of so-called civilisation is the way in which contact with its vices secures the extermination of primitive tribes. The case of the rapidly disappearing Eskimos is pathetic in the extreme, and it is pleasing to record that one of their strongest friends and champions is an English medical man, Dr. Grenfell. In former times the natives of the frozen country of Labrador wrung a livelihood out of their barren surroundings by the aid of native weapons and by dint of hard and adventurous living. Now, as a matter of fact, they are being rapidly exterminated from the face of the earth by the continued ravages of hunger and disease. Armed with modern weapons of civilisation, they have killed off the herds of musk ox merely for the sake of their skins. In that way they have destroyed their main source of food-supply. Then, again, they are being decimated by syphilis, introduced by the crews of the whaling ships. Whole tribes are said to have been destroyed, in some instances under terrible circumstances. It seems clear that the countries that send the whalers are morally responsible for this result. Why should not the wanton spread of syphilis be a punishable crime? Canada has forbidden the export of musk ox skins, so that the natives should not exterminate them for the sake of the hides. It would be well if the legislation of that Dominion would deal with the evil of syphilis in an equally prompt and decisive manner.

Slums and Coroners.

The Truro Coroner has taken a step that bids fair to have somewhat far-reaching consequences. In a case under investigation in which death was attributed to bad surroundings, the Coroner called in some prominent members of the sanitary administration of the town, and after requesting them to inspect the premises concerned, called them as witnesses. It would be hard to imagine a more dramatic and effectual way of bringing home to those responsible for the local sanitary welfare a conviction of their own shortcomings. Were object-lessons of this sort to become general, we venture to predict that the terrible evil inflicted upon the community by the owners of slums would be speedily abated. For one thing, it is obvious that evidence of the kind would have an inestimable value in tenants' actions for damages for injury to health and life through insanitary premises, of which several have been successfully conducted in recent years. As irremovable and independent Crown officials, the coroners are almost the only persons able to fight such strongly-vested private interests as those interested in slum property and patent medicines. The owners of bad houses have long ago recognised the advantage of being strongly represented on local governing bodies. It is not likely, however, that they would survive many pillories in the Coroner's court. It is to be hoped that the example of the Truro Coroner may be followed by his brethren throughout the United Kingdom.

Indian Hospital Assistants' Journal.

We have received a copy of a new medical journal which gives us peculiar pleasure, namely, the *All-India Hospital Assistants' Journal.* The hospital assistants have formed an Association which, in their own words, "aims at the scientific, moral, and material progress of our class," and the journal is the organ through which the members scattered over the vast peninsula are kept in touch with one another and instructed. That the hospital assistants desire improvement and are capable of forming such an Association and editing such a journal must give great satisfaction to those who sympathise with the native aspirations in India, and wish to see a happy, well-governed, and prosperous people in that Empire where England has such vast responsibilities. The surest path of progress is through the practice of self-culture and the assumption of responsibility, and we warmly congratulate the hospital assistants on their enterprise, which, if wisely carried out, will be a source of help to the officers of the Indian Medical Service under whom they serve, just as the organisation of professions and trades at home is of assistance both to the members and those with whom they come into contact. The number of the journal before us speaks with appreciation of the Indian Medical Service, and the official approval of the movement is testified to by the patronage of highly-placed officers. In connection with the movement against quackery which THE MEDICAL PRESS AND CIRCULAR is constantly keeping alive, it is interesting to us to read in a paper by Mr. P. S. Ramchandrier, of Ahmedabad, the following passage:—"I do not like to omit what I have to say about your duty to put down the charlatan in the stations you will be in charge. This is most rife in India. It is wonder to me how this benign Government which takes superb care to prevent any ordinary man not to practice law without professional course in a recognised institution, allows scot-free men veneered with sanctimonious theories of medicine to practice their arts on slaughtering the ignorant and poor agriculturists. What is not done by the ruling power, people like us can to a certain extent do for ourselves." An autocratic Government like that of India ought to grapple with the question soon and strongly; it is not beset with the difficulties met with in this country. It strikes the British reader curiously to read of a concession granted to the assistants. "Hospital assistants are not required to fire a revolver course" runs a new regulation. Perhaps the quacks will be glad too. But, revolvers or no revolvers, we stretch out the hand of welcome to our native fellow-subjects.

Infantile Mortality at Huddersfield.

THE endeavours of the municipal authorities of the borough of Huddersfield to cope with the evil of infant mortality have within the past year or two attracted much public interest. By virtue of a special Act which came into operation exactly a year ago, the Corporation has had, during the past twelve months, special powers it did not previously possess, and it is interesting to note the effect of the working of this Act. Under it all births have to be notified to the health authorities within forty-eight hours, and it appears that 94 per cent. of all the births have actually been so notified. All the exertions of the health authorities are in the definite direction of helping the mother to nurse her child in her own home. On the notification of each birth, a medical woman, assistant to the medical officer of health, calls at the address given, and if advice as to infant management is needed, she gives it. Ladies, who act as honorary visitors, give their help, and, where necessary, continue to supervise the care of the infant. No dole of any kind is given, either by the visitors or by the municipal authorities. The results have been better than anyone could have hoped. The infant mortality rate for the first nine months of the year has been 85, whereas for the corresponding period of last year it was 138, and the mean for ten years was 135. Comparing the mortality in Huddersfield with that in other towns a great difference appears. In the third quarter of the year the infant mortality rate in the seventy-six towns of the Registrar-General's list was 110; that of Huddersfield was 62. We congratulate the municipal authorities on their magnificent success, and we wish that other towns would follow their example. It is stated that the pecuniary expenditure for this saving of infant life has not exceeded £400 a year!

Appendicitis and Plum-pudding.

WHAT is the relation of plum-pudding to appendicitis? Lest the question should shroud the Christmas season with an appalling gloom, we hasten to say that there is no appendicitis in plum-pudding. The grotesque theory still propounded by some kill-joys that pips in the pudding cause appendicitis is a hoary turnip-headed scarecrow. So far from upsetting the digestion, there can be nothing finer, more digestible, nourishing, toothsome, and sustaining than good, wholesome English plum-pudding made from a sound recipe. Let mothers take this kindly medical advice to heart. It is not the plum-pudding that hurts the child, but rather the stuffing with fruit and comfits and lollipops and candies and other of the rich cates that cluster round the merry Yuletide. Let a healthy youngster abstain from these things between meals, and let the meals be plain, then there will be no need to shun the plum-pudding on Christmas Day. For it is clear to the plain man as to the 'pothecary that plum-pudding hath its scientific as well as its grossly material and fleshy aspects. It is from our love and veneration of this finest of old English dishes that we would point out to our fellow-countrymen of all ages, all sexes, and all temperaments, how to enjoy to the utmost the brief but all-conquering season of its advent. We lay it down as a law of the Medes and Persians that no plum-pudding has half the heavenly savour of that served up in Christmas week decked with a sprig of berried holly and wreathed in lambent flame. So mote it be to all of us!

The British Medical Association and its Charter.

WE have before now commented on the question of the British Medical Association petitioning for a Royal Charter, and we have advised the members to exert due caution before committing themselves. For several months a warm debate on the subject has been in progress, and at the present time a referendum is being taken to settle the question. The official journal, which is working hard for the Charter, in this week's issue makes a quotation from the legal adviser of the Association which may or may not help towards that object. Mr. Beaufort Palmer says that if the Association were under a charter instead of being, as at present, governed by the Companies Acts, it "would be freed for all practical purposes from the trammelling rules of the Courts in regard to what is and what is not *ultra vires*." In other words, the property and interests of the members would not be so securely safeguarded as at present. This might be a very serious matter, as it would be difficult to rectify an unwise action. The members will be wise to watch any further developments which would emancipate the governing body "from the trammelling rules of the Courts." Incidentally, we may notice that the debate on the question has brought about a curious position in the Association, in that the Council and the representative meeting have found themselves in disagreement, and the duel system of government of the Association established a few years ago has not worked well.

The Reform of the Irish Poor-Law.

The Chief Secretary for Ireland has during the past week informed an influential deputation which waited upon him that the Irish Government were drafting a measure dealing with Poor-law reform, that it had first place on their list, and that it would be proceeded with as soon as ever time could be found for it. Further, he stated that the recent report of the Viceregal Commission would furnish a basis for the proposed legislation. As our readers know, one of the most important recommendations made by this Commission was the conversion of the existing Poor-law Medical Service into a State Medical Service. This proposal was cordially supported by the Irish medical Colleges, the Royal Irish Academy of Medicine, the Irish Medical Association, and other kindred organisations. The necessity for some such step has been fully recognised, and almost its only opponents are the various local boards which would lose opportunities of patronage. Human nature being what it is, such opposition is only natural, and surely it ought not to be allowed to weigh against a measure so urgently demanded in the interests of the Irish poor. Mr. Birrell, in his reply to the deputation, referred to the fact that so many of the recommendations of the Commission were contentious. He, however, above all men, should not shrink from what he considers necessary, because he must by this time know that nothing in Ireland which is worth anything is free from contention.

Defaulters under the Midwives Act.

The working of the Midwives Act is now advanced far enough to warrant some sort of conclusion as to its future progress. The "Association for Promoting the Training and Supply of Midwives" is already appealing to the public for a vast sum of money to enable the training of midwives to be conducted on a national scale. Where the matter will end is a subject for speculation, but there appears to be a not altogether remote prospect that eventually medical men will find themselves faced with the competition of an army of pseudo-medical practitioners. At present the fear is more than justified by the terrible roll of indictments against 33 midwives presented last week before the Central Midwives Board. Several women were accused of administering medicines other than a simple aperient without entering the fact upon a register. One woman is stated to have administered a vaginal douche with a syringe previously used to give an enema. A number of cases of drunkenness were on the list. Failure to report puerperal fever occurred in many instances, and often nurses continued attendance on other labours while infected from a puerperal case. Neglect to call in medical men formed a large proportion of offences; in the majority of instances the midwife failed to seek such assistance for puerperal fever; but there were several cases of ruptured permanent or retained placenta in which she apparently considered the advice of a medical man superfluous. It will, of course, be argued by the supporters of the Act, that these cases simply prove the need of special training and of rigid supervision. While that may be admitted it nevertheless seems no less clear that the contentions of the medical men are being amply justified when they asserted that certificated midwives would infallibly regard themselves in many cases as entitled to carry on a sort of hybrid quack medical practice under the ægis of their diploma.

PERSONAL.

Dr. Robert Maguire has been installed as Master of the University of London Lodge of Freemasons.

Dr. John C. S. Rashleigh, of Par Station, Cornwall, have been nominated a Sheriff for that county.

Dr. Thompson. of Feeny, has been placed on the Commission of the Peace for the County of Londonderry.

The award of the Nobel Prize for Medicine has, as anticipated, been made to Dr. Laveran, of the Pasteur Institute.

Dr. James MacLachlan has been re-elected Provost of the Dornoch Town Council for a further period of three years.

It is announced that Lord Cromer has accepted the office of honorary vice-president of the Liverpool School of Tropical Medicine.

On his retirement from the Liverpool Royal Infirmary, Mr. Rushton Parker's students, past and present, are presenting him with his portrait in oils.

Dr. William Berry has been presented with a silver tea service in recognition of his twenty-five years' service as Honorary Secretary to the Wigan Medical Society.

Professor Moritz Schmidt, of Frankfort, who recently was the recipient of the title of "Excellency" in recognition of his services to laryngology, has, we regret to hear, recently died.

The annual dinner in connection with the Medical School of the Birmingham University was held at the Grand Hotel on December 10th. The chair was occupied by Dr. J. W. Russell.

Dr. Charles James Sutherland has been promoted to be a Knight of Grace of the Order of the Hospital of St. John of Jerusalem. A similar distinction has been conferred on Lieut.-Colonel E. J. Hunter.

Dr. Arthur J. Hall, Physician to the Sheffield Royal Infirmary, has been appointed Lecturer on Practical Medicine in the University of Sheffield, rendered vacant by the resignation of Dr. W. Tusting Cocking.

The medical men of Old Withington have presented Dr. Railton with a silver rose bowl on the occasion of his retiring from the office of Medical Officer of Health of the district, which post he had held for 35 years.

Dr. Alexander James was entertained at dinner by numerous medical friends on the occasion of his retirement from active service as Physician to the Edinburgh Royal Infirmary. Dr. Underhill, President of the Royal College of Physicians, occupied the chair.

With the advent of the New Year Dr. A. Wynter Blyth will cease to hold the post of Medical Officer of Health of Marylebone, still retaining, however, that of local Public Analyst. His successor in the medical officership is Dr. Meredith Young, Medical Officer of Stockport.

The Right Hon. the Earl of Meath, K.P., P.C., H.M.L., Co. and City of Dublin, with the approval of his Excellency the Lord-Lieutenant of Ireland, has been pleased to appoint Mr. William Askin Shea, of "Elmville," 5, Garville Avenue, Rathgar, and 28, Westland Row, to be a Deputy-Lieutenant of the City of Dublin, in place of Charles E. Martin, Esq., D.L., deceased. Commission dated December 7th, 1907. Mr. Shea is a J.P. of the City of Dublin and Vice-Chairman of the South Dublin Poor Law Board of Guardians and Registrar of the Incorporated Dental Hospital, Dublin.

A CLINICAL LECTURE
ON
FRACTURES AT THE WRIST. (a)

By D'ARCY POWER, F.R.C.S.Eng.,

Surgeon to and Lecturer on Surgery at St. Bartholomew's Hospital; Surgeon to the Bolingbroke Hospital, and Consulting Surgeon to the Victoria Hospital for Children, Chelsea.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GENTLEMEN,—I propose to talk to you to-day about fractures at the wrist, illustrating my remarks by skiagraphs, for which I am indebted to our X-ray department, which is so excellently managed by Dr. Lewis Jones and Dr. Walsham, though I am the more especially indebted to Mr. J. M. Flavelle for the trouble he has taken in selecting from the common stock so splendid a series of illustrative plates. If I had chosen this subject ten years ago I should have spoken of it as "Fractures of the Lower End of the Radius," and when I used to teach you the elements of fractures and dislocations more than twenty years since, we merely called it "Colles' fracture."

By taking advantage of successive advances in physics and surgery we have achieved very satisfactory results in diagnosis, and where we used to employ a specific name we are now obliged to reconsider the nomenclature and sub-divide the injuries at the lower end of the wrist into a variety of groups, which may be thus tabulated:—

Radius.	Separated lower epiphysis.		
	Unimpacted fracture.		
	Impacted fracture.	Simple.	Colles' fracture.
		Lower fragment comminuted.	
	Oblique fracture through articular end without comminution.		
	Styloid process detached.		
Ulna.	Separated lower epiphysis.		
	Fracture of shaft in lower third.		
	Styloid process detached.		
Scaphoid.	Simple fracture.		
	Fracture with dislocation of one fragment.		
Radius and Ulna.	Transverse fracture.		
	Colles' fracture with styloid process of ulna torn off.		
Radius and Scaphoid.	Colles' fracture with fractured scaphoid.		
Ulna and Scaphoid.	Fracture of Scaphoid with tearing off of styloid process of ulna.		

I need hardly call to your notice the clinical features which are common to a broken wrist. You all know the picture which you see so often in the surgery. A patient, rather pale and shaking, who holds one wrist tightly grasped against his chest by the other, and pushes open the door with his shoulder. He says that he has just fallen and sprained his hand. It is very painful, and quite useless. Examination shows that the wrist is deformed and bent to the radial side, so as to reveal the lower end of the ulna with unnatural clearness. Movements of pronation and supination are impossible, or are made by an awkward twisting of the arm from the shoulder or elbow. Closer examination shows that the deformity is due to a bony swelling in a typical case, the swelling being more marked on the dorsum than on the palmar surface.

Yet, with all these marked signs and symptoms, it is remarkable how long a fracture of the lower end of the radius escaped notice, for it seems to have been looked upon as dislocation of the wrist, a form of injury which is very rare. Abraham Colles was not quite the first to call attention to the true nature of the injury, but he was the first to describe it so simply and accurately as to make it his own, and to render his name one of the household words in surgery. I hold in my hand his original paper. It is dated from St. Stephen's Green, Dublin, 1814. It is less than four pages in length, and it appeared in the *Edinburgh Medical and Surgical Journal* for the year 1814 Vol. X., p. 182). The paper begins:—"The injury to which I wish to direct the attention of surgeons has not, as far as I know, been described by any author. Indeed, the form of the carpal extremity of the radius would rather incline us to question its being liable to fracture. The absence of crepitus and other common symptoms of fracture, together with the swelling which instantly arises in this as in other injuries of the wrist, render the difficulty of ascertaining the real nature of the case very considerable." Colles then describes the clinical signs, and adds a few comments on the prognosis and treatment. It is interesting to notice that a surgeon of such gigantic experience as Sir Astley Cooper was not clear as to the mechanism of the fracture, although he had examined broken wrists post-mortem. Colles' explanation passed current, and without much criticism, until 1842, when Voillemier stated that he believed that impaction was essential in fractures at the lower end of the radius, a conclusion which was criticised adversely by Prof. R. W. Smith in 1847, and was adjudicated upon by Prof. E. H. Bennett in 1879, who found that both writers had been too absolute in their statements.

A.—SIMPLE FRACTURE OF THE LOWER END OF THE RADIUS.

I show you a skiagram of a perfectly simple fracture of the lower end of the radius within a quarter of an inch of the carpus. It shows clearly the mechanism of such an injury. The scaphoid and the semi-lunar bones in the proximal row of the carpus are closely connected with the articular surface of the radius; whilst the cuneiform bone is separated from the lower end of the ulna by the triangular fibro-cartilage. When a patient falls upon his outstretched hand, the whole force of the shock comes upon the lower end of the radius, and it is transmitted rather obliquely because, as the skiagram shows, the axis of the wrist is itself slanting. The pressure, therefore, is exerted upon the outer or styloid-process side of the radius. The skiagraph shows further how weak the lower end of the radius is as compared with the shaft of the bone, for the expanded end of the radius is cancellous tissue, with a thin covering of compact bone, whilst the shaft is compact bone without much cancellous tissue.

The next skiagraph shows a transverse fracture of the lower end of the radius in a patient whose lower epiphysis is not yet united. It shows, too, why such fractures are rare in children, Colles' fracture being essentially a fracture of adult life. In a young person the shock of a fall upon the hand is distributed by two buffers—first, the elasticity of the epiphysis, and, secondly, the intermediary cartilage which lies between the epiphysis and the shaft forming the growing part of the bone. In young persons, therefore, a severe injury is saved to the radius, but may be transmitted further up the arm, causing a backward dislocation at the elbow, or even a broken collar-bone.

B.—IMPACTED FRACTURE OF THE LOWER END OF THE RADIUS.

The next plate shows the condition which we recognise as typical of a Colles' fracture. The radius is broken close to its carpal extremity, and the lower fragment has been penetrated by the upper fragment in such a manner that the upper fragment is driven obliquely into the lower extremity. There is no comminution of the lower fragment; the styloid process of the ulna and the lower end of the ulna are both uninjured. A closer examination of the plate shows that the impaction of the fracture has occurred, so that the upper fragment enters the lower obliquely from above downwards, the lower extremity being driven upwards, backwards and outwards. The impaction, moreover, is not complete, because the cancellous tissue of the lower fragment does not contain both layers of the compact tissue of the upper fragment, and there is clearly inter-penetration. This is seen in the side view of the wrist, and is not shown in the antero-posterior skiagraph. It is well, therefore, to have two views of every broken wrist, one taken with the hand flat and one in profile.

(a) Delivered at St. Bartholomew's Hospital on Wednesday, November 27th, 1907.

C.—COMMINUTED FRACTURE OF THE LOWER END OF THE RADIUS.

When the violence leading to a broken wrist has been considerable, the lower end of the radius may be comminuted, as is shown in this skiagraph. I called attention to this form of fracture so long ago as 1887 (*Trans. Path. Soc.*, Vol. XXXVIII., p. 250), and our museum contains several excellent instances of it. This plate shows the lower fragment split vertically into two pieces, but without much impaction, and with no injury to the ulna. Such an additional injury renders the prognosis more serious, because the carpal joint is involved, and the wrist may easily become stiff unless it be recognised and measures be taken early to counteract its effects.

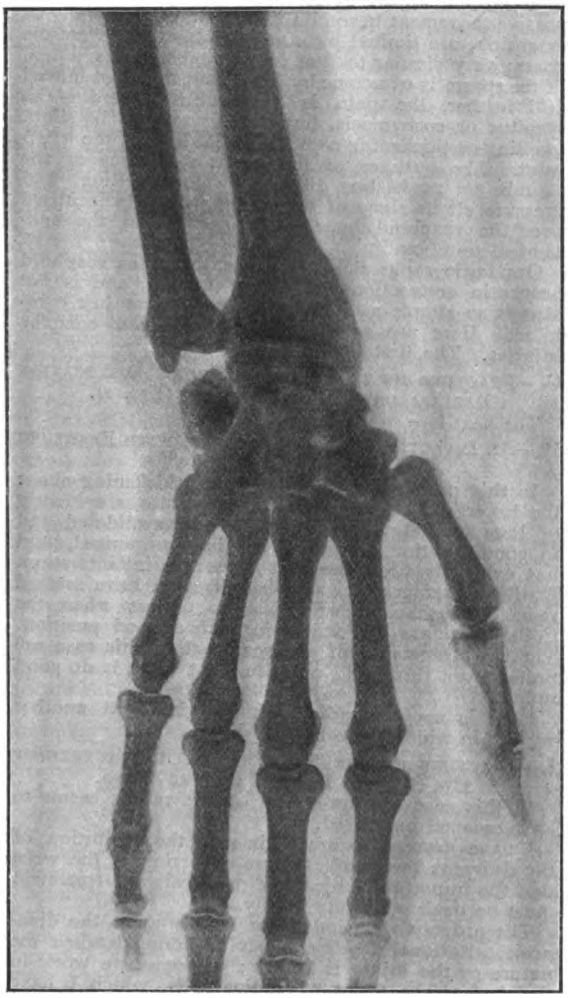

FIG. 1.—SIMPLE FRACTURE OF THE SCAPHOID, WITHOUT DISPLACEMENT OF EITHER FRAGMENT.

These fractures were practically all the forms of broken wrist recognised before the advent of skiagraphy, but, as our scheme shows, several additional forms are now clearly recognised.

D.—OBLIQUE FRACTURE THROUGH THE CARPAL ARTICULAR SURFACE OF THE RADIUS.

The next radiograph shows an entirely different form of fracture. Half the articular surface of the radius is separated from the other half by a line of fracture extending from the scapho-lunar facette obliquely outwards, and ending at some distance above the base of the styloid process. A slighter form of fracture which was probably only recognised as a bad sprain is seen in this radiograph, where the styloid process of the ulna is separated without injury to the articular surface. In neither of these fractures has there been any injury to the ulna.

E.—FRACTURE OF THE STYLOID PROCESS OF THE ULNA.

In these skiagrams the styloid process of the ulna has been torn away, whilst the radius is intact. It is plain that the fracture of the styloid process is not always at the same spot, for in one radiograph it is a mere nodule of bone which has been detached, whilst in these the whole styloid process has been torn off. It appears most probable that such fractures of the styloid process of the ulna have generally been looked upon as bad sprains of the wrist until radiographs showed their true nature.

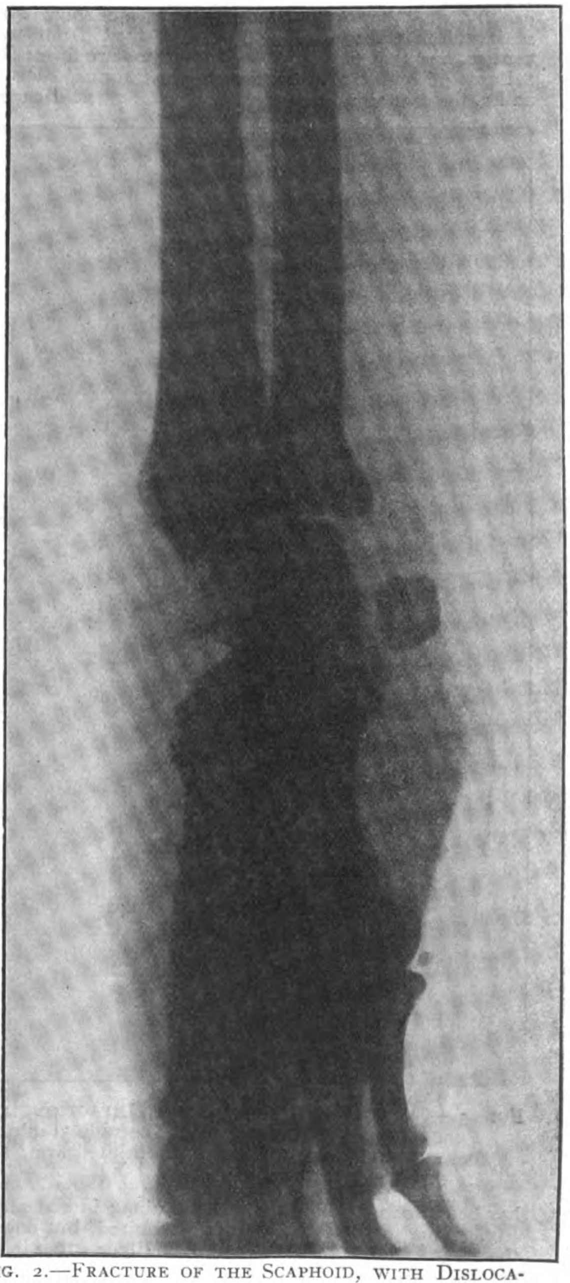

FIG. 2.—FRACTURE OF THE SCAPHOID, WITH DISLOCATION OF ONE FRAGMENT.

F.—FRACTURE OF THE SCAPHOID.

The next group of radiographs shows an interesting series of fractures of the scaphoid, fractures which have hitherto been very little known, but which are evidently not uncommon, for here are several different plates showing similar appearances.

The scaphoid, as you well know, is one of the larger bones of the carpus partially curved upon itself and traversed obliquely by a groove. It is easy to imagine that under pressure from the os magnum and the articular surface of the radius the scaphoid would be broken into two fairly equal fragments, and the figures 1 and 2 which are reproduced from the radiographs I show you prove that this is exactly what happens, although there are some who maintain that the scaphoid is developed from two centres, and that these apparent fractures are in reality failures of ossification. In the simplest forms, Figs. 1 and 3, the scaphoid is merely fractured, and no damage has been done to the radius or the ulna; in one plate, Fig. 2, the scaphoid is not only fractured, but one of the fragments has been displaced bodily, so that it lies on the dorsum of the wrist. This displacement would have been overlooked if the radiographer had omitted to take two pictures of the wrist, one flat, the other in profile, so that here is another instance of the importance of taking more than one view of every fracture.

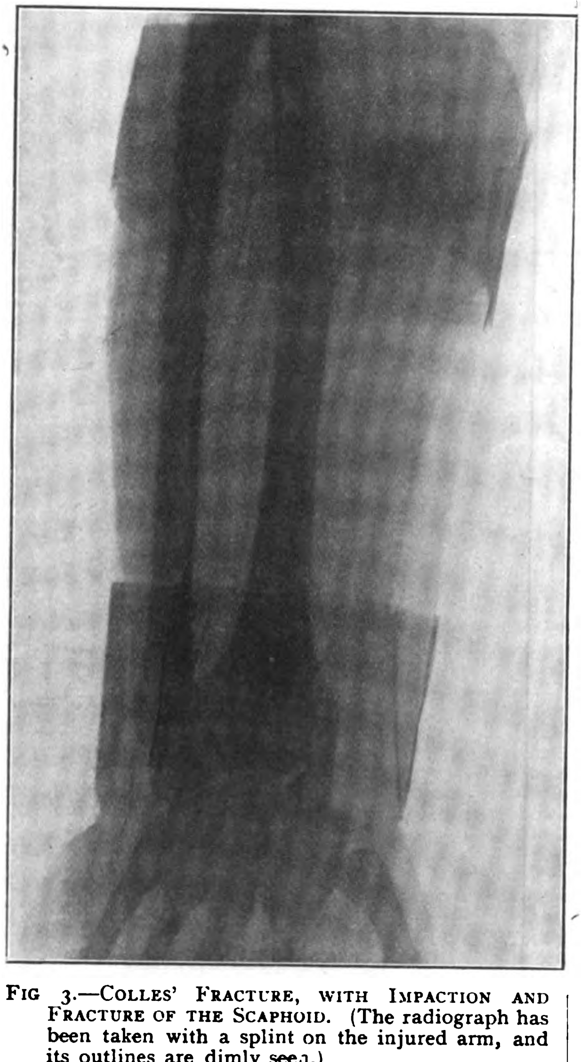

FIG 3.—COLLES' FRACTURE, WITH IMPACTION AND FRACTURE OF THE SCAPHOID. (The radiograph has been taken with a splint on the injured arm, and its outlines are dimly seen.)

Drs. Codman and Chase, of Boston, Mass., have published a most excellent monograph on the diagnosis and treatment of fracture of the carpal scaphoid and dislocation of the semi-lunar bone. It appears in *The Annals of Surgery* for 1905, Vol. XLI., and from their account I take the following passages:—"The patient, usually a male of from twenty-five to thirty-five years of age, has fallen on his extended wrist in the same manner as in the injury which usually causes a Colles' fracture. He has supposed that he has sprained his wrist, and for a few days has suffered severe pain and tenderness, and has been unable to use his hand for ordinary purposes. During a period varying from a few days to a few weeks, according to the hardihood of the individual, he has refrained from using his wrist. Gradually he has been able to take up his work again, but after a certain point the soreness, tenderness, and disability have refused to improve. Eventually he comes to the hospital complaining of pain, tenderness and weakness of the wrist. Examination shows that the fingers have their normal flexibility, but that the active and passive movements of the wrist-joint are limited to one-half or less of their normal arc of excursion. Attempts to continue passive movement beyond a certain point, especially in extension, are limited by a most characteristic muscle spasm very similar to that seen in tuberculous joints. If the spasm is overcome by force, and the wrist moved still farther, the pain is intolerable. There is no crepitus or ecchymosis, but there is seen to be slight swelling or thickening over the radial half of the wrist-joint. The outlines of the extensor tendons of the thumb are made less distinct by the swelling, and pressure elicits signs of tenderness definitely localised over the scaphoid bone, and specially in the anatomical snuffbox."

Our radiographs show that fracture of the scaphoid occurs in connection with other injuries, and is not always so simple as in the pictures I have just exhibited. Here are several varieties of such complex injuries. The first one is—

G.—FRACTURE OF THE SCAPHOID, WITH DISLOCATION BACKWARDS OF ONE FRAGMENT (FIG. 2).

The next is—

H.—AN IMPACTED COLLES' FRACTURE, WITH FRACTURE OF THE SCAPHOID.

In this case there has been some thickening about the lower end of the ulna. The fracture is evidently of long standing, for the radius is consolidated and in good position, but the wrist is disorganised, and has evidently been the seat of severe inflammation. Until the skiagraph was taken it must have seemed remarkable that the wrist was so useless when the Colles' fracture had united in such a good position. The two fragments of the scaphoid in this case are united by a thin band of callus, but there is no good union.

Here is another radiograph showing still another variety in which there is—

I.—FRACTURE OF THE SCAPHOID, WITH FRACTURE OF THE STYLOID PROCESS OF THE ULNA.

In this case the lower end of the radius seems to have escaped uninjured.

I have devoted so much time to the exhibition of the different forms of fracture occurring at the wrist that the important subjects of prognosis and treatment must be dealt with very briefly.

The prognosis depends very largely upon the diagnosis. Rational treatment can be adopted when the nature of the injury is known; otherwise we work in the dark. The series of radiographs which I have shown you warn us that fractures at the wrist are often complex, and that it is impossible to obtain a satisfactory result when such an injury is treated on the supposition that it is "only a Colles" or "merely a sprain," because the additional injury has been overlooked. It is important, therefore, to obtain a good radiograph in every case, and at the risk of "damnable iteration" I would repeat in more than one position of the limb. Broadly speaking, the prognosis is good in simple fractures at the wrist when the styloid process of the radius or ulna is not torn off, or when the fracture of either or both bones is simple and transverse. In Colles' fracture with impaction it is fairly good even when the lower fragment is comminuted, but in fracture of the scaphoid it is bad unless the injury is recognised at the beginning and treated accordingly. But the arm is needed for much more delicate movements than the leg, and therefore I would personally much rather sustain a Pott's fracture than have a broken wrist.

The first essential of treatment is to leave nothing to chance, but to bring the broken ends of the bone into the very best possible apposition, and keep them there until they are united. The impacted end of a Colles' fracture should always be separated before a splint is applied. I make this an absolute rule for your guidance. There are a few exceptional conditions where it is better to sacrifice some of the use of the wrist and leave the ends impacted, but they do not concern you now, and it is best for you to remember that every Colles' must have the deformity completely reduced as soon as possible. A Carr's splint must then be applied. It is the best form of splint for these fractures, because it is easy to make with a straight splint, to which a piece of a broom handle is screwed obliquely, and it is comfortable to wear. The fingers are bound round the end of the splint until the acute pain and some of the inflammation have subsided, and this is usually for four days. The fingers are then left free, though the splint is still bound to the hand and wrist. Once a day the surgeon or nurse moves each finger deliberately and in succession, so as to ensure the free movement of the long flexor and extensor tendons in their sheaths as they pass over the injured wrist, for in these fractures the tendon sheaths are often damaged by the presence of inflammatory products. At the end of a month the splint may be safely replaced by a leather wristlet, or in a poor person by a small bavarian splint, reaching from the point above the fracture to the middle of the hand, and the patient should be instructed to use and exercise his wrist joint, more especially by movements involving some rotation at the joint. The joint should be rubbed from the tenth day onwards if it is possible to secure skilful massage. The gauntlet may be dropped at the end of the fourth week from the accident.

But this treatment is not useful for cases of fractured scaphoid. The two fragments of this bone show very little power of union, and it is therefore necessary to take more active measures.

A fractured scaphoid is generally taken for a sprain when it occurs as the only injury to a wrist, and it is often several weeks before the patient has a radiograph taken. This may account for some of the bad results. But in the radiograph I showed you the fractured scaphoid was only a part of other injuries which must have made the immediate application of a splint a matter of absolute necessity. The radius in this case was firmly united, but the two fragments of the scaphoid are only joined by a slender thread of callus. An attempt may be made to obtain union when the scaphoid has been broken, but if at the end of a month the radiograph shows that it has not occurred satisfactorily, the patient should be advised to have one of the broken pieces removed. Experience has shown that if the united fracture is allowed to remain, the wrist becomes the seat of a chronic inflammation which makes it painful and increasingly useless. The removal is made through a small incision on the dorsum of the wrist parallel to and along the inner side of the tendon of the extensor carpi radialis longior. When one fragment of the scaphoid is dislocated, as in Fig. 2, there should be no hesitation in removing it at once.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Dr. Chantemesse, Professeur Agrégé of the Faculty of Medicine of Paris. Subject: "The Serum Treatment of Typhoid Fever (Antityphoid Opsonisation)"*

The witnesses before the Royal Commission on Vivisection last week were Dr. Swan and Dr. Cowen, on behalf of the National Canine Defence League; Mr. A. G. Scott and Sir F. Banbury, M.P., on behalf of the Royal Society for the Prevention of Cruelty to Animals; Mr. L. E. Shore, M.D., Physiological Laboratory, Cambridge; and the Hon. Stephen Coleridge, re-called, on behalf of the National Anti-Vivisection Society.

ORIGINAL PAPERS.

CASES DEMONSTRATING THE VALUE OF SPINAL ANALGESIA IN PROTECTING THE PATIENT FROM SURGICAL SHOCK.

By E. CANNY RYALL, F.R.C.S.I.,

Senior Surgeon to the Kensington General Hospital.

The object of this paper is to bring before the notice of our surgical *confrères* the absence of shock when operations such as those recorded in the following cases, amongst others, are performed under the influence of lumbar puncture.

When one considers the fatalities resulting from shock following operative interference, it is of the greatest importance to eliminate this factor, and we believe that in spinal analgesia we have the method for combating it—a method which, we regret, has not yet received the due consideration in this country which it deserves.

In these cases no pain was felt during the operations. Headaches and vomiting were absent, and the result as regards shock was ideal in all instances, notwithstanding that two of the patients were suffering from severe heart lesions, and in a third pulmonary tuberculosis in an active stage already existed.

Case I.—Suprapubic Prostatectomy.—Heart Disease.

J. K., æt. 60, first came under our care as an out-patient at the Kensington General Hospital in 1906, and gave the following history. About two years ago he began to be troubled with frequency of micturition and difficulty in starting the act. He often had pain, referred to the glans penis, and had noticed blood in his urine on two occasions. For the past two months the frequency increased, and he is now compelled to micturate every hour during the day, and to rise three or four times each night. Occasionally he has had sudden stoppage of the flow of urine.

On examination per hypogastrium nothing abnormal could be detected. Per rectum the prostate was found to be enlarged, smooth, of uniform consistence, and movable. When asked to micturate it was noticed that the stream was small and ejected with little force. After the act he was placed on a couch, his glans penis and meatus thoroughly washed, and a sterile rubber catheter passed, which drew off 3 oz. of residual urine which was alkaline, sp. gr. 1025, containing pus cells and crystals of calcium oxalate, but no blood or albumen. He was subsequently admitted into hospital as an in-patient, and on passing a cystoscope we found the prostate enlarged, and lying in the post-prostatic pouch was an oval-shaped calculus. He was kept confined to his bed and placed on a light diet. His bladder was washed out daily, and urotropine administered in combination with acid sodium phosphate, This had the effect of rendering his urine acid in reaction, and practically free from pus. He had a well-marked mitral regurgitant murmur, an impulse diffused and feeble, and a pulse of low tension. Bronchial râles could be heard over both lungs. Under these circumstances we considered that general anæsthesia should be avoided, and determined to operate under spinal analgesia.

The day preceding the operation we ordered 4 minims of liquor strychninæ to be injected hypodermically every six hours.

Operation.—On October 11th, 1906, the patient was anæsthetised as follows: He was seated on the operating table with his body bent forwards, the interval between the third and fourth lumbar spines defined, and the puncture point marked with pencil. Ethyl chloride was then sprayed on the site of puncture, and the needle of our syringe, which was made for us by Messrs. Allen and Hanbury, plunged into his spinal canal. Three cc. of a 5 per cent. isotonic novocain-suprarenin solution, containing novocain 0.15 g., and suprarenin borate 0.000325 g., was then injected, and the patient placed on his back. The bladder was then well washed out with boric lotion, and 12 oz. of suprarenin solution injected into the organ as the distend-ing medium. This solution we have now used in suprapubic prostatectomy for some years, with the object of controlling hæmorrhage and preventing shock.

Analgesia being complete over the abdomen, we made an incision above the pubes, opened the bladder, removed a calculus the size of a pigeon's egg, and then enucleated the prostate. The amount of blood lost was very small. The bladder having been again washed out, a drainage tube of 1 in. in diameter was inserted into the bladder, and gauze, covered with cellulose wadding, applied to the wound. The patient was then taken back to bed, and sensibility had returned in abdomen and legs one hour afterwards. During the operation a running conversation was kept up with the patient.

After-Treatment.—His bladder was irrigated twice daily, both through the wound and urethra; urotropine and acid sodium phosphate were given medicinally. He had no sickness or headache following the operation, and made an uninterrupted recovery, leaving the hospital bright and cheerful.

It appears to us that suprapubic prostatectomy performed under spinal analgesia with novocain opens up a new field in the surgery of this organ. We were particularly struck in this case, the patient being an extremely nervous subject, suffering from advanced heart disease, as well as in many other prostatectomies performed under lumbar puncture, with the absence of shock which is so commonly met with following this operation under general anæsthesia: and we would strongly urge operating surgeons who are in the habit of performing suprapubic prostatectomy under chloroform or ether to give this method a trial, for we feel certain that if the after-effects following the operation are as slight in their cases as they have been in ours, they will seldom make use of general anæsthesia.

CASE 2.—STRANGULATED FEMORAL HERNIA.—PHTHISIS.

A. J. K., æt. 33, was admitted into the Kensington General Hospital, on April 13th, 1907, suffering from strangulated femoral hernia. On examination, a swelling about 3 in. long by 2 in. broad could be felt in the region of the femoral canal, which was tense, tender, and without impulse on coughing. Pulse 96, small and wiry.

Frequent vomiting was present. He was very much emaciated, and both lungs were the seat of tuberculous deposit. He was suffering from shock, and his general condition most unfavourable for general anæsthesia.

A few hours after admission into hospital his dural sac was injected with 8 cc. of a 1 per cent. solution of novocain-suprarenin, 8 cc. of cerebro-spinal fluid having been first withdrawn. Five minutes afterwards herniotomy was performed. The intestine which occupied the sac was slate-coloured.

He stood the operation extremely well, and his general condition improved immensely, but, unfortunately, his lung trouble caused his death eleven days later.

CASE 3.—STRANGULATED INGUINAL HERNIA.

A. P., æt. 45, was admitted into the Kensington General Hospital in a very collapsed condition, suffering from a strangulated inguinal hernia.

His trouble commenced 24 hours before admission by the expulsion of a large mass through the inguinal canal into the scrotum. He was vomiting for several hours before he sought relief at the hospital. On examination he was found to have a large tense swelling extending from the lower part of the scrotum into the inguinal canal, which was very tender and without impulse on coughing, and could not be reduced by taxis. Herniotomy was performed an hour after his admission under spinal analgesia; 10 cc. of a 2 per cent. novocain-suprarenin solution was injected in the mid-line between the second and third lumbar vertebræ, 10 cc. of cerebro-spinal fluid having been first withdrawn and discarded. Ten minutes elapsed between the injection and the commencement of the operation, during which time a final washing of the field of operation was carried out. The sac contained a small portion of intestine, together with a large bulk of omentum. The latter was tied off in sections, and excised. The constricting ring was very small and tense, and after its division the gut and stump of omentum were replaced into the abdomen, and the wound closed in the usual way. The patient's condition during the operation was surprising. His collapsed appearance vanished, and he left the operating-room in a far better state than when he entered. He was discharged cured.

We have had similar cases of strangulated inguinal hernia which have had herniotomy performed under spinal analgesia, and in each instance there was an entire absence of shock following the operation.

CASE 4.—CARCINOMA OF RECTUM.—HEART DISEASE.

E. C., æt. 55, an extremely nervous patient, was first seen at my house on April 4th, 1907, when he stated that he had to go to stool about twenty times in the 24 hours, passing motions which were small in size, generally semi-fluid, containing mucus and blood. He was found to be suffering from advanced arteriosclerosis, with double aortic murmurs, and the apex beat displaced downwards and outwards. He had marked throbbing in the femoral and carotid arteries.

When about to make a rectal examination, we were particularly struck with the small size of his anus, and directly it was attempted to put the finger into the canal he could not bear it, although there was no fissure or other sign of disease at the orifice. It was only after using a local anæsthetic that we were able to make a momentary examination of the rectum, which revealed carcinoma, for, owing to the sensitive condition of the patient, it was impossible to make the thorough examination necessary for our guidance as to the advisability of recommending excision of the growth.

Five days later a thorough examination of his rectum was made under the influence of spinal analgesia with novocain. It was then found that the growth was fixed to the surrounding tissues, and the lumen almost obliterated. Excision was therefore out of the question, and an inguinal colostomy was advised, and subsequently performed six days afterwards. On this occasion he was also given a spinal injection, consisting of 10 cc. of a 2 per cent. novocain-suprarenin solution. Before the injection 12 cc. of cerebrospinal fluid was withdrawn by syringe suction and thrown away. Analgesia was perfect in three minutes. He bore the surgical interference well, and was chatting to us during the operation.

Within three weeks he returned home, with the artificial inguinal opening working satisfactorily.

Six days later profuse hæmorrhage from the growth in the bowel took place, and as the rectum required plugging, a third injection of novocain into the lumbar sac was given, and the bleeding arrested.

Finally, two days afterwards, a fourth lumbar puncture was made, and novocain-suprarenin solution injected. Analgesia having been produced, the gauze plugging was removed. The patient was so nervous and sensitive that he refused to allow any interference to be carried out without a spinal injection.

As this patient was suffering from severe aortic disease, and his own medical attendants refused to give him a general anæsthetic owing to the risk involved, one had therefore no hesitation in using spinal injections, and on each occasion it worked admirably.

CASE 5.—CARCINOMA OF RECTUM.—EXCISION BY THE SACRAL ROUTE.

J. M., æt. 57, was admitted into the Kensington General Hospital on September 20th, 1906, suffering from carcinoma of the rectum.

For several months prior to admission he had suffered from a constant desire to go to stool, and although he passed fluid motions containing blood and slime, he still felt a sensation as if there were something in the bowel to come away. On examination per rectum a malignant growth could be readily detected involving the circumference of the bowel, and extending beyond the reach of the finger. It was freely movable on the underlying tissues.

On September 21st the operation of colostomy was performed, and he was discharged from the hospital within a month. Before leaving, the question of excising the growth and its danger were fully discussed with him, but he could not make up his mind to have the second operation done.

On November 12th, 1906, he was re-admitted for excision of the rectum, having determined to undergo the risk of operation with the prospect of getting rid of the disease. Preparatory treatment for a few days having been carried out, on November 15th excision of the rectum by the sacral route was performed under the influence of spinal injection with 2 per cent. novocain-suprarenin solution. The operation involved the removal of the coccyx as well as the lower end of the sacrum. About 8 in. of the terminal end of the gut, including the anus, were excised, which necessitated freely opening up the peritoneal cavity. From the beginning to the end of the operation the patient frequently assured us that he could feel no pain, and throughout its performance no paleness or other change could be detected in his facial aspect. His pulse was 84 at the commencement of the operation, and 86 at its termination.

When the operation was completed and he was taken back to bed, his bright appearance and jocular manner was a complete surprise to those who saw him. He left the hospital well. We have seen him a few days ago, and there is no sign of recurrence of the growth, a period extending over twelve months having elapsed since the operation.

THE TREATMENT OF SYPHILIS IN THE LIGHT OF THE RESULTS OF RECENT INVESTIGATIONS. (a)

By E. LESSER, M.D.,
Professor of Dermatology, Berlin.

[Specially Reported for this Journal.]

Gentlemen,—Recent times have procured for us two great steps in advance as regards syphilis—the communicability of the disease to animals, and the discovery of the excitors of it by Schaudin, and the further labours of Hoffmann. By these the subject of syphilis has been placed upon quite a different basis as regards diagnosis and treatment, as these now have a basis of certainty as regards origin and animal experiment. The question, therefore, has now to be discussed: What influences have these advances had upon our views? I shall only touch upon the chief points, and shall discuss them chronologically.

First comes the much-discussed question of the excision of the primary sore. By excision are we in a position to remove all the virus, and thereby protect the system against general infection? Undoubtedly the chances are greater the earlier the excision is carried out. But, great as the chance was, the uncertainty of diagnosis was up to now greater still—so much so that we could not decide as to whether excision had prevented the general infection, or whether this would not have come on without it. Now, by proof of the spirochetæ, we are in a position to make the diagnosis early, and so form a groundwork for answering the question of the efficacy of excision. The histological examinations and animal experiments are but little encouraging as regards any good prospect from excision. But as Jadassohn properly remarks, the conditions in the inoculation of apes are different from what they are in man, and it is also to be considered that after removal of many excitors of the organism, after the analogy of other infective diseases, the comparatively few remaining excitors may suffice for further infection. That is true with one exception so far, that Finger, after excision in one case that was diagnosed with certainty, saw no secondary symptoms during two years.

A second question is: What is to be done after the excision? Formerly general treatment was not begun if there was no induration of the cicatrix, and no appearance of general secondary symptoms was indicated. Now, however, it is recommended that general specific treatment shall be begun immediately after excision if spirachetæ are found, as we cannot be sure that all the virus has been removed by the excision. Repeated courses, even, have been carried out. Thalmann has injected a 1 per cent. solution of sublimate under the primary sore with good effect. Before this, even, Weisspflug had injected a 1 per cent. solution of salicylate of mercury into the glands in 32 cases, and in 28 of them saw no secondaries after the lapse of some years. Thalmann, however, always associated his local treatment with general, so that his cases do not serve for answering the question on this point, and the large number of injections of Weisspflug are to be looked on as general treatment.

The third question is: When shall the general treatment be begun? Formerly, most were of opinion that it should be begun as soon as secondary symptoms made their appearance, for the reason that, if begun earlier, the diagnosis might be masked. We did not know whether the absence of secondary symptoms was spontaneous or due to the general treatment; whether specific induration had been present or not. Now by demonstration of the spirochetæ we can diagnose a primary sore with certainty, and masking need no longer be feared. Then it was assumed that the result of the general treatment was better when the first appearance of the general symptoms was waited for. Now the question comes up whether with earlier general treatment the virus may not be destroyed in its place of first localisation, or whether, if this cannot be done, the general symptoms, when they do appear, are not rendered milder by it. Neisser and Thalmann advocate early treatment. According to my view the question cannot be decided yet, as the time is at present too short. The better effect of general treatment after the appearance of the general symptoms has been attributed to the organism being flooded with the virus, and being thereby more accessible to attack. This view must, however, be looked upon as incorrect. From the searching investigations of Hoffmann, however, it may be taken that the flooding of the system with the virus precedes the outbreak of the general symptoms by about three weeks. According to this, mercurial treatment should be begun at this period

A fourth question concerns the intermitting general treatment for protracted periods introduced by Fournier. Most specialists have adopted this mode of procedure. As regards its propriety in the period before the discovery of the spirochetæ, in the Festschrift for Senator I attempted to put it on a basis, after Lang's method, in the following manner: The form and kind of fever show that when the infection is general, the virus is latent for a time, then, after apparent recovery, it again becomes active, because only a part of the virus has been destroyed. The latter circumstance is the cause why, in relapses, the number of disease centres becomes steadily less. The latter rule is, however, subject to one exception, that the germs present everywhere in the body break through direct into the circulation, and so lead to a sudden flooding of the system with the virus. It must therefore be the aim of all rational treatment to destroy all the disease germs.

Does mercury, then, act destructfully on the spirochetæ? According to Thalmann, the answer is yes. In favour of this is the fact that in many cases fever comes on after even the first application of the drug. The question can only be decided with certainty by the direct application to the spirochetæ. In some cases Hoffmann saw rapid disappearance of the spirochetæ after injections of sublimate, in other cases the germs were found afterwards. That mercury destroys the spirochetæ cannot be doubted, but the destruction is not always complete, even when the treatment has been protracted, as we sometimes see relapses after it. Hence the desire to find another more certain remedy. This has not been obtained yet, however, for even iodine, good as it is in the treatment of syphilis, is no substitute for mercury. The desire for a substitute for the latter is justifiable on account of the injurious effects associated with it. Here also the discovery of the excitors of the disease has led us farther on. After the action of atoxyl on various forms of trypanosoma had been established, Uhlenhuth tried it for the destruction of the spirochetæ in syphilis. The experiments first performed on apes were encouraging; then it was tried in my own clinic on two patients who were given a number of injections of atoxyl in 0.2 gm. doses. The result was negative. Lassar met with the same want of success. Later on appeared the communications of Salmon, in which atoxyl in large doses was said to be followed by brilliant results. Upon this Uhlenhuth gave doses of 0.5 gm., and satisfied himself of the good effects. Lassar also recorded recoveries with the high doses. In my own clinic I treated 28 patients with the drug (22 men and 6 women); 3 were in the primary stage, 19 had secondary, 5 galloping, and 1 tertiary syphilis. In every case a 10 per cent. solution of 0.5 to 0.6 gm. of atoxyl was injected into the muscles. A total amount of 5 to 6 gm. of atoxyl was given in each case. The result as regarded the disappearance of symptoms was good, frequently quite striking. The primary affections receded rapidly, the secondary more slowly; an iritis healed after three injections. The effects were striking in ulcerations in malignant syphilis, in sclerous glossitis, in syphilitic angina. A myelitis disappeared very rapidly after 6 injections. No specific local treatment was made use of in any case; for ulcerations, dressings of solutions of acetate of alum were applied. Sometimes a solution of atoxyl was painted on with good effect. In three cases the results were unfavourable; in one a relapse took place after 14 days. Along with these generally favourable results, however, symptoms of intoxication by atoxyl could not be overlooked. Considerable accessory effects were not unfrequently observed, such as violent colic-like pains, with loss of appetite and sleeplessness, nausea, vomiting, diarrhœa, and once nephritis with albumin and cylinders in the urine. These symptoms disappeared when the medicine was left off, and in every case returned when it was begun again. In the case of one woman opium had no effect on the vomiting and diarrhœa; no effect was produced until morphia was given with bicarbonate of soda. The observations must be continued. It was known that when other preparations of arsenic were given, arsenic was discoverable after some days, and now in one case arsenic could be found six weeks after it had been given. Generally considerable increase in weight took place after the use of atoxyl, but in three cases a loss of weight was shown, so that as a rule the effect as to nutrition was not unfavourable. After all, the verdict must be that atoxyl causes a rapid disappearance of the symptoms of syphilis, and that therefore it may be very properly made use of in cases of individual susceptibility to mercury. A conclusive judgment cannot be pronounced at present, however; that can only be done after years of trial. We must ever keep one thing before our eyes—that the risks of a remedy, however effective, must not be carried too far.

THE NEW MEDICAL SERVICE FOR THE TERRITORIAL ARMY. (a)

By SIR ALFRED KEOGH, K.C.B.,

Director-General of the Army Medical Service.

THE scheme, Sir Alfred said, is one which has been really devised by the Volunteer medical officers themselves. So long ago as 1901 a meeting of Volunteer medical officers at Edinburgh put forward practically every one of the proposals embodied in the official scheme, and more recently, at another meeting of Volunteer medical men, practically the same suggestions were then made. When he took up the position of Director-General of the Army Medical Service, his attention had been first occupied with the organisation of the Volunteers, because, as was well known to every student of military medical organisation, the existing state of affairs was far from satisfactory. There was now a declared military policy of a definitely scientific character, under which there would be an expeditionary force equipped to take the field abroad at a moment's notice; and in the absence of that expeditionary force the whole responsibility of home defence would be undertaken by the Citizen or Territorial Army. The absence of the expeditionary force implied the removal of the regular medical service of the Army, which was not, as a matter of fact, sufficiently large for the purposes of completely satisfying the needs of the expeditionary force, but was large enough to form a sufficiently good nucleus. The whole responsibility for the medical arrangements of the Citizen Army, if there were an invasion during the absence of the Regular Army, would devolve upon the medical profession. The leaders of military thought were thoroughly wide awake to the immense importance of the relation which the medical service bore to the Army. There was a time when this was not so, but military science was now being studied, and it was now clearly realised that the battles of the future were not going to be won simply at the point of the bayonet, but by the different sciences composing the Army. The duty of the medical service might be summed up in the phrase—the maintenance of the fighting strength of the Army. Our Army being comparatively a small one, made the prevention of wastage of fighting force in the field a factor of enormous value in the winning of battles. There were some who would say that there would never be any invasion, or even any threat of invasion. It was in the same spirit of unpreparedness that we had entered into all our previous wars; and, although we had always been victorious in the long run, we had invariably muddled them at the beginning. Sir Alfred proceeded to give, with the assistance of diagrams, a sketch of the operations of an Army medical organisation in the field, explaining briefly the duties of the various departments of the organisation and the system by which they were linked up. He laid particular emphasis on the value of what he described as business aptitude, and said that if the service were inefficient in this respect the wastage of the fighting force would become exceedingly rapid. Military experts calculated that the wastage of strength in our Army in the first year of a war was 80 per cent. of the total strength. A large part of this was to be attributed to medical shortcomings—lack of knowledge as to the origin and spread of disease in camps and insufficient inspection of the men in hospital, many of whom were not sent back to fight when they were fit to take their place in the line. Large numbers of men were returned home from South Africa in the late war who ought to have been in the ranks. They had heard a great deal of Army scandals in connection with that war, but, in his opinion, there were no scandals, except possibly that the supervision was inadequate to prevent a great amount of wastage. Our system of disease prevention and sanitation was defective in one respect—that the officers who were charged with the care of the hospitals were also charged with the sanitation of the surrounding area. That was utterly impossible, and for the correction of this defect they had the beginnings of a sanitary service, in connection with which there was a sanitary school at Aldershot, which in course of time would prove to be a great advantage. Another proposal was that a sanitary committee of business men should follow the troops in time of war, and assist the medical staff on the spot, instead of holding a commission of inquiry after the battle. That kind of committee would be welcomed by the medical staff. They did not do much that was wrong, and, taken all round, their performances in the South African war were a credit to the profession. In the existing medical service of the Volunteers, in many battalions there were four or five medical officers and no hospitals whatever. They had trained a number of men to pick up the wounded and to carry them. What they were going to do with them after picking them up, and where they were going to carry them, nobody could say. Civil hospitals would not do for the accommodation of the Citizen Army. If a small army of 70,000 men were sent to Liverpool, and had to be kept under canvas, it would only be a matter of a few days before there were 2,000 or 3,000 on the sick list. That condition would grow in intensity until—quite apart from epidemics—there would be 10 per cent. of the men in hospital. Obviously the civil hospitals could not accommodate them, especially as during a time of invasion there would be great depression and distress, and the hospitals would hardly have room for them.

There was no sanitary service whatever connected with the Volunteer Forces, and the conditions of the

---

(a) Address delivered before a representative gathering of medical men at the Town Hall, Liverpool, on December 10th, 1907.

Volunteer Army had been admirably adapted to the exclusion of a large number of the leaders of the profession in medicine, surgery, and sanitation. Everybody who attached himself to the Volunteers was required to go into camp to make himself efficient—as if a leading physician would make himself more efficient as a physician by going into camp. It was a silly system, which was to be held responsible for many of the shortcomings of the Volunteer medical service.

Proceeding to the explanation of the medical staff scheme connected with the Territorial Army, Sir Alfred said there were to be eleven specific areas recognised under the scheme, and every division would have a medical officer on the staff of the general, from whom he would receive his orders and convey them to the staff in his area—thus securing co-ordination in the medical and military movements. With a chief medical officer of each division there should be a sanitary officer. With each battalion there should be a sanitary organisation. He proposed that every sanitary officer in the country should be asked to join that force. Without an efficient sanitary service it would not require foreigners to bowl our Territorial Army over, for when they were mobilised—coming as they did from all quarters and from all conditions of life—disease would break out much more rapidly than in an encampment of Regulars, who would come straight from the barracks, where their health was under constant supervision. He proposed also that there should be twenty-three general hospitals at the great educational centres, so that the aid of the most eminent experts in the profession could be obtained; three field ambulances, consisting of nine medical officers and a quartermaster and 230 non-commissioned officers and men, would also be required in each division. The organisation of the field ambulance would imply work in time of peace, but Liverpool had great facilities in connection with its special schools, hospitals, and educational institutions. The conditions of service would be exceedingly simple. Those who could not go into camp would be asked to do eight days' training of some kind. The days would not necessarily be consecutive, and three hours would compose each day. A consolidated corps to embrace all this was proposed for the purpose of carrying out the duties which would devolve on the medical profession in time of invasion.

CLINICAL RECORDS.

BELFAST HOSPITAL FOR CHILDREN.

CASES SHOWN AT THE LAST MEETING OF THE ULSTER MEDICAL SOCIETY, DECEMBER 12TH

By John McCaw, M.D.Dub., F.R.C.S.,

Physician to the Belfast Children's Hospital.

Evelyn M., æt. 10 years. Admitted to Children's Hospital on November 22nd, 1907. Child began to complain of headache and some cough 14 days ago. On admission nothing amiss could be found but a small patch of dulness on the right side behind on a level with middle of right scapula. Temperature has been sub-febrile since admission, never rising higher than 100° F. She was submitted to Calmette's ophthalmo-reaction, and responded markedly. This is likely tubercular enlargement of a tracheo-bronchial gland. Under treatment she has improved in general condition.

Violet W., æt. 2 years and 2 months, was admitted to hospital on November 6th last with well-marked symptoms of tetanus. The jaws are strongly set, temperature 103°. pulse 156, risus sardonicus very well marked. Antitetanic serum, obtained from the Lister Institute, London, was injected into the left abdominal wall, the dose given being 5 c.c. This was repeated on November 8th, 11th, and 16th. A notable feature was the high rate of pulse, which ranged from 180 to 160 till after the third injection of serum. On the night of the 7th, restlessness became extreme; chloral hydrate was given up to 8 grs., without effect; chloroform was then administered with good results, and she slept after it till next morning. The restlessness returned next night; chloroform was again given in small quantity, and with the same beneficial effect. The following day the spasm of the jaws was much relaxed, and she was able to swallow from a spoon, and tube feeding was omitted. After this the symptoms gradually subsided, and she made a perfect recovery. There was no wound on the body, and the only septic focus was a spot or two like impetigo on the right thigh.

Robert N., æt. 8½ years. Has complained of pain in the forehead for the last year at intervals. Latterly this pain has become much more obtrusive, and is now accompanied with well-marked cerebral vomiting. He has not had any convulsive seizures at any time; no optic neuritis. Tested with Calmette's ophthalmo-reaction, he reacted. Much improvement has followed the exhibition of pot. iodide gr. 5, with liq. hydrarg. perchlor. ½ drachm ter in die. This may be a caseous tuberculous tumour in the cerebellum. Still under treatment in hospital.

James T., æt. 9 years, was admitted to Children's Hospital 6 days ago with well-marked local asphyxia in the hands and feet, some small blisters on the feet and marks of many others that have healed. He has improved very much under 10 gr. doses of chloride of calcium.

OPERATING THEATRES.

VICTORIA HOSPITAL FOR CHILDREN.

Widespread Peritonitis from Sloughing of Appendix.—Mr. J. Cunning operated on a boy, æt. 9, who had been admitted for pain in the abdomen and fæcal vomiting. The illness began five days before with sudden abdominal pain accompanied by vomiting. His mother called in a doctor next day, who gave him castor oil. He passed a motion after the castor oil, but the vomiting and pain continued, and the vomit became fæculent in smell. On the fifth day he was admitted to the hospital. He looked very ill with a pain-pinched face and sunken eyes; his pulse was 140, his temperature 101. The abdomen was not distended, but was board-like in rigidity all over. No lump could be detected on account of the rigidity and extreme tenderness on pressure. There had not been passage of either blood or mucus. Mr. Cunning remarked that he had to deal with a case of widespread peritonitis; the persistent vomiting and its fæculent character indicated that there was intestinal obstruction; intestinal obstruction is either inflammatory or mechanical, and the extreme rigidity and tenderness was a clear indication that this was inflammatory. The absence of distension at this stage was unusual; it put out of account any question of the obstruction being mechanical. The absence of blood and mucus being passed from the rectum also put out of account intussusception as the lesion. The diagnosis of appendicitis was, therefore, the most likely one. At the operation the theatre was heated to a temperature of 80, and the patient was laid on a table heated by hot water cans, with as little exposure as possible. The abdomen was opened by an oblique incision midway between the umbilicus and the anterior superior spine on the right side. Foul smelling thin pus was evacuated. On passing a finger into the abdominal cavity, the appendix was found in Douglas's pouch; it was pulled up into the wound, and it was discovered that the terminal inch was black and gangrenous, and just proximal to the gangrenous portion was a fæcal concretion. The appendix and its mesentery were ligatured and removed. There were some indications of limitation by adhesions towards the mid line both in Douglas's pouch and in the main part of the abdominal cavity, but the pus was found to extend upwards in the renal pouch towards the liver. A second incision was made in the loin, and tubes were passed in one towards the liver and one into Douglas's pouch. As it was not known whether the other side of the abdominal cavity was affected, the right side was covered with dressings and clean gloves were donned. An incision was then made on the left iliac fossa, where pus was again found, both in the pelvis and up towards the spleen. A second tube was passed down into Douglas's pouch, and another was passed in through the left loin towards the spleen. Dressings were then applied, and the patient sent back to the ward, where continuous rectal saline was administered. The whole operation lasted fifteen minutes. Mr. Cuming said that this was a case in which suppuration had extended from the appendix into the pelvis, and then the pus had followed the usual definite tracks, that is, it had overflowed into either the renal pouch upwards towards the liver and the spleen leaving the main central portion of the abdominal cavity unaffected. These were the cases which were usually spoken of as general peritonitis when they recovered, but, of course, they were not general but only widespread. As soon as the patient recovered from the anæsthetic he would be propped up in the sitting position, so that the pus might drain from the more susceptible upper areas to the less susceptible pelvic area. The administration of saline solution by the continuous rectal method was a great help in the saving of these cases: the larger the amount of fluid absorbed the more chance there was of eliminating the toxins, and eight or nine pints in the twenty-four hours could be easily taken up by this method. With regard to the gangrene of the appendix he thought the concretion had produced either an abrasion or an actual ulcer: this formed a focus of entry of a virulent brand of either bacillus coli or streptococci which had caused so much inflammation and exudation that the circulation of the terminal inch of the appendix had been cut off. It should be remembered that the terminal third of the appendix had no mesentery, and that its circulation had to be carried on by vessels running along its wall, so that any violent inflammation at or about the termination of the mesentery, if it produced much swelling, would cut off the circulation beyond that area.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Clinical Section.

Meeting held December 13th, 1907.

The President, Sir Thomas Barlow, in the Chair.

Dr. Edgar Reid (introduced by Prof. W. Osler) showed a case of

OCHRONOSIS.

F., æt. 68. A large ulcer on each leg had been dressed twice daily with carbolic oil, 1 in 20, during a period of 30 years. Six years ago the ears and whites of the eyes began to turn black, and two years ago the urine was first noticed to be dark. In June, 1907, the concavity of each ear was stained a deep blue-black, and the sclerotics were stained black in their exposed portions. The extensor tendons of the fingers were bluish-black in colour over the knuckles, and the latter showed a slight blue staining. The skin of the face and exposed parts was of a dusky hue as compared with the covered parts.

Prof. Osler discussed the case, and pointed out that carbolic acid poisoning had been noted in the four last recorded.

Dr. A. E. Garrod had examined the urine, and, from the observation that 85 per cent. of the sulphates were in the aromatic form, had concluded that the patient was a potential carboluric, although no carboluria was actually present. He remarked that all the previous cases had had either carboluria or alkaptanuria—*i.e.*, one or other hydrokinone derivative, and this pointed to a common origin for all the cases.

Dr. Parkes Weber discussed the early diagnosis of such cases, and pointed out the confusion that might arise between cyanosis and hæmatochronosis.

Prof. William Osler showed a case of

SPLENIC POLYCYTHÆMIA WITH CYANOSIS.

Patient was a hard-working woman, in whom, within the past two or three years, there has been slight failure of health and strength. She was permanently cyanosed. She presented in an unusual degree the three characteristic features of the disease: a permanent cyanosis, a greatly enlarged spleen, and a polycythæmia of 10,000,000 red blood corpuscles. There was no increase in the leukocytes, and no marked variation in the size of the red blood corpuscles. There were nucleated red cells in moderate numbers, chiefly normoblasts.

The first case of this kind had been published by Vacquez. Since Prof. Osler's paper in 1903, some 40 or 50 had been recorded.

Dr. R. G. Hann referred to a case characterised by great splenic enlargement, polycythæmia, recurrent attacks of diffuse abdominal pain, but with no cyanosis.

The President considered that the absence of cyanosis in Dr. Hann's case excluded it from the present group. He referred to a case he had recently seen in which the vasomotor changes were very marked.

Dr. Parkes Weber mentioned that in one of his cases there had been a great number of normoblasts. In all the autopsies so far there had been found infarctions with perisplenitis, which might account for the occurrence of abdominal pain.

Dr. William Pasteur had had a case recently of splenic enlargement accompanied by periodic abdominal pain. Post-mortem there was neither infarction nor perisplenitis.

Mr. T. H. Openshaw showed a case of

TRAUMATIC DISLOCATION OF HIP, IN A BOY OF 15, REDUCED BY MANIPULATION AFTER THIRTEEN MONTHS.

Dr. F. Parkes Weber showed a case of

ARTERITIS OBLITERANS OF THE LOWER EXTREMITY, WITH INTERMITTENT CLAUDICATION.

M., æt. 32. Complained of cramp-like pains in the sole of the left foot and calf of left leg, occurring after walking for a few minutes and obliging him to rest. When the legs were allowed to hang over the side of the bed the distal portion of the left foot became red and congested-looking. No pulsation could be felt in the dorsal artery of the left foot or in the posterior tibial. The disease had lasted about five years, without real gangrene supervening.

Dr. W. Essex Wynter showed a case of

METHÆMOGLOBINÆMIA OF TWELVE YEARS' STANDING.

F., æt. 45. (Under observation since March, 1902.) Had been in the same state of cyanotic anæmia for twelve years. There was a general yellowish pallor, with lilac-coloured mucous membranes, associated with feebleness, constipation, anorexia, and occasional vomiting. A pulmonary systolic bruit existed while the patient was in hospital. Urine normal. Blood chocolate-coloured, making comparison difficult in the hæmoglobinometer; the colour was not altered by exposure to CO; red cells, 3,010,000; white cells, 7,000; hæmoglobin, 50 per cent.; index, .74; white corpuscles normal; bacillus coli not found in blood.

Dr. Poynton had seen this case at St. Mary's Hospital twelve years ago, and the condition was then, if anything, worse than to-day.

Dr. C. R. Drysdale asked whether there was evidence of blood destruction in this case, as sometimes occurred.

At the President's suggestion, a committee consisting of Dr. Drysdale, Dr. Garrod, Dr. Poynton, and Dr. Wynter was appointed to investigate the case further.

Dr. W. Essex Wynter showed a case of

AMYOTONIA CONGENITA.

F., æt. 15 months. Admitted to Middlesex Hospital, September 21st, 1907, on account of general weakness and backwardness. The striking feature in the condition was the flabbiness of muscles and freedom of movement in articulations, allowing of flexion and extension beyond normal limits, so that the toes could be made to touch the front of the leg and the fingers the back of the forearm, while the legs could be flexed up to the chin. The child could sit up and walk, and was cheerful and intelligent. The muscles did not contract to strong faradism, and moderate currents induced no pain.

Dr. **Morley Fletcher** raised the doubt that the case might be one of severe rickets affecting chiefly the muscles.

Dr. **Ernest Jones** remarked on the deviation from the title of myotonia, originally given by Oppenheim, to the condition.

Dr. W. **Essex Wynter** showed a case illustrating

CURE OF ASCITES BY PERMANENT DRAINAGE THROUGH THE FEMORAL RING.

M., æt. 50. Admitted to Middlesex Hospital, July 11th, 1907. For a week there had been swelling of abdomen and legs, with slight jaundice. The diagnosis was hepatic cirrhosis. The ascites increased, and on August 26th tension was relieved by removing 300 ozs. of fluid. This was only of temporary benefit, and on September 23rd Mr. Sampson Handley made a small incision below the umbilicus and several pints of fluid escaped. An incision as for femoral hernia was then made, and with the aid of one finger in the abdominal cavity the process of peritoneum was drawn down, split, and the edges stitched right and left to maintain the opening. The wounds were then closed. The ascites did not recur, and by November 20th there was no perceptible fluid in the abdominal cavity. The patient had been walking about the ward for a fortnight, and neither femoral hernia nor œdema of the leg had developed.

Mr. **Sampson Handley** described the operation. He had had to open the abdomen so as to reach the femoral ring.

Dr. W. **Pasteur** showed a case of

ANTERIOR POLIOMYELITIS, WITH PERMANENT PARALYSIS OF THE DIAPHRAGM AND ABDOMINAL MUSCLES.

M., æt. 13½. Illness began in November, 1906, fever and delirium. Two days later there was loss of power in lower limbs; paralysis spread, and mother noticed that boy could not cough; arms not completely paralysed. On admission on eightn day, November 19th, there was flaccid paralysis of the lower limbs; the diaphragm was paralysed; respiration entirely thoracic; abdominal muscles paralysed; abdominal and epigastric reflexes absent; paresis of all muscles of upper limbs. For ten days the condition was critical; artificial respiration performed every two or three hours; inhalations of oxygen and hypodermic injections of strychnine given frequently. From March until the present time the condition had remained as follows: complete recovery of power in upper limbs; considerable recovery of thoracic muscles; persistent paralysis of diaphragm, abdominal muscles, and muscles of lower limbs.

Dr. F. J. **Poynton** showed

TWO CASES OF THYROID SWELLING IN YOUNG GIRLS.

The first was a typical case of Graves's disease in a girl æt. 15. The second case was that of a girl æt. 14 who had been treated for cretinism as an infant. Whenever thyroid treatment was omitted within six weeks, the following symptoms appeared: (1) a swelling in the neck, obviously the thyroid; (2) mental dulness; (3) slowness of speech; (4) enlargement of the tongue. Resumption of the thyroid caused the disappearance of all these symptoms.

Four weeks ago the patient, who has been steadily treated ever since these attempts, showed a definite thyroid swelling. There were no symptoms of Graves's disease. At present no increase had been made in the amount of thyroid given, and the neck still showed the swelling.

The diagnosis inclined to is partial cretinism, with compensatory enlargement of an inefficient thyroid to supply the lack of secretion when the outside supply is slowly cut off.

Dr. J. **Graham Forbes** showed a case illustrating an unusual form of gouty deposit in the left olecranon bursa in a man æt. 34. No evidence of gouty deposit about great toe joints.

Prof. **Osler** remarked that such deposits might be the only sign of gout apart from even the usual tophi.

Dr. Poynton said that microscopically it was clear that the primary change in these cases was a necrotic one, and that the deposit was secondary.

Dr. **Parkes Weber** contrasted the cases in which the reaction to irritation was mainly a fibrous one with these in which marked tophaceous deposit occurred.

Dr. **Garrod** thought that surgical measures in such cases were valuable provided the joints were not involved. The olecranon bursa was a favourite site for tophaceous deposit.

Dr. H. **Batty Shaw** showed a case of

BULBAR PARALYSIS.

F., æt. 47. For twenty years had had a large bronchocele and slight attacks of periodic huskiness of the voice. In June, 1907, half the bronchocele was removed, as the pressure on the trachea was increasing; it presented the microscopic structure of carcinoma.

July 8th, voice almost completely lost; stridor; weakness of left lower facial muscles. July 15th, pain and stiffness of back of neck. August 21st, atrophy of right half of tongue noted. August 28th, diplopia. November 5th, paresis of sixth nerve on right side, paresis of right half of palate, paresis and atrophy of the right sterno-mastoid and trapezius; aphonia; could swallow solids with difficulty; paresis of left lower facial muscles and complete paralysis of left vocal cord; vomiting had recently occurred. The diagnosis lay between primary degeneration of the centres of the various nerves involved, possibly due to thrombosis, and a secondary deposit in and about the medulla. The latter view was supported by the presence of severe pain and stiffness of the muscles of the back of the neck.

Dr. H. **Batty Shaw** also showed a case of

HEPATO-SPLENOMEGALY WITH ASCITES.

F., æt. 3½, was noticed to be short of breath in June of this year. She was now easily tired and unable to walk far owing to shortness of breath. The abdomen was observed to be swollen on November 22nd of this year, and this has increased steadily.

There were no signs of tuberculosis or of syphilis. The liver was enlarged and the spleen was felt easily. Jaundice had not been observed.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, November 29th, 1907.

Mr. E. H. Taylor in the Chair.

Intrameningeal Hæmorrhage.

Mr. R. Atkinson Stoney presented a patient whom he had trephined for intrameningeal hæmorrhage. The following were the notes of the case:—Patient, L. M., æt. 44, admitted to Royal City of Dublin Hospital on Tuesday, September 3rd, 1907. History of falling on back of head in street while drunk the previous Saturday; he seemed none the worse at the time. On Sunday evening began to get drowsy and stupid; this condition was increased on Monday. On admission he was dazed and stupid; he could not speak properly; started to answer a question, and then began to talk nonsense; pupils were equal, contracting to light; pulse, 65-70; temperature, 99°; very restless; no mark of injury; complained of pain in right occipital region; reflexes normal. On Thursday patient seemed better; speaking more distinctly; still very restless. Continued to improve till Tuesday, 10th, when he began to get drowsy and stupid again. He was worse on Wednesday. On Thursday morning quite unconscious; pulse over 100; colour somewhat blue; pupils equal; very sluggish. In the middle of day pupils very small, equal, not reacting; pulse over 120 and very weak; moving all his limbs; knee-jerks absent; Babinski's sign present on both sides; saw patient twitch right arm once; did a lumbar puncture, and drew off a test tube full of clear fluid; slightly relieved by this for about half an hour, then got worse again. Trephined over left parietal eminence; dura mater bulging, dark blue, and not pulsating; on opening it found a thin layer of clot and dark fluid blood; could not feel any laceration or fracture, though felt both petrous portion of temporal bone and orbital plate of frontal. At end of operation pupils were larger, reacting to light, and brain pulsating; pulse, however, was bad, but improved after infusion of three and a half pints of saline solution; patient was better in the evening; swallowed a few mouthfuls of milk with difficulty. On the next day (Friday) pupils were reacting; complete paralysis of right arm was found; knee-jerks absent; plantar reflexes normal; pulse varying from 100 to 120. On Saturday, very bad in early morning; at 1.30 pulse was 140 and very weak; bad colour, and respirations bad; dressed the case; flap was very prominent, not pulsating; on taking down the flap, found no clot, but brain was prominent and not pulsating; vessels were congested; put a needle about two inches into brain and drew off test-tube full of clear fluid under considerable tension; brain receded somewhat and pulsated feebly; eyes reacted better; pulse and colour were better. When dressed next day, flap not so prominent; appeared slightly conscious; recognised wife and brother. Gradually improved, and began to use right hand on Tuesday. On following Sunday a note to say can use right arm well. At present patient appears in perfect health; normal movement of arm; but some difficulty in pronouncing some words and complete inability to read, though able to write and recognise all objects.

The **Chairman** asked if there was any hæmorrhage going on during the operation, and whether it was on account of the oozing of blood that the drainage tube was introduced. He was also anxious to know if Mr. Stoney's view of the bulging of the brain afterwards was that it was due to distension of the lateral ventricle, or whether he considered there was any œdematous condition of the brain tissue itself. Mr. Stoney had not stated the cause of the marked depression of the scalp over the area corresponding to the part that had been removed.

Mr. **Blayney** said the case was a puzzling one, in view of the history that had been given. The typical history of intrameningeal hæmorrhage was that the patient became unconscious, and did not become conscious again; but in the case before them the patient did not lose consciousness when he met with the fall. One would imagine that violence sufficient to produce hæmorrhage inside the skull would have caused unconsciousness. Then there was a prolonged period in which there were no signs of increased intracranial tension. He thought the bulging of the brain after the operation was due to some inflammatory phenomenon.

Mr. **Stoney**, in reply, said he had brought the case forward in the hope of eliciting some explanation of the sequence of events, as he had to confess he found it difficult to do so himself. The history had been difficult to obtain, as the man was drunk at the time of the accident, as well as everyone who was with him. So far, however, as he could make out, there was no loss of consciousness at the time of injury. When the signs of increased pressure began to appear, he thought it was the commencement of œdema of the brain, and he was under the impression that operation offered little hope of improvement, but he felt that the localising signs justified an attempt to find out their cause. On opening the dura mater there appeared to be no fresh hæmorrhage, and on exploration he could find no laceration and no fracture. He was doubtful as to whether the hæmorrhage occurred at the time of the injury, the symptoms of increasing compression being due to œdema of the brain, or that the hæmorrhage had occurred later on and was producing the symptoms of pressure by itself. He thought the protrusion of the brain was mainly due to the collection of fluid in the lateral ventricle. A useful point in the case was the fact that it showed that the descriptions in the books of typical cases of intrameningeal hæmorrhages could not be entirely relied upon. It showed also that cases of head injury should never be looked upon as hopeless.

Mr. W. I. **de C. Wheeler** exhibited a case of ascites from hepatic cirrhosis cured by the Talma-Morison operation performed three years ago. The patient had been frequently tapped before the operation, and drained through an exploratory laparotomy wound, but without any beneficial result. For about three weeks after the epiplopexy fluid collected, and a small amount has persisted, neither getting more nor less for the past three years. The patient, who weighed about 7½ stones before operation, now averaged 11 stones. The amount of fluid withdrawn by paracentesis before the radical operation was performed approximated two gallons per fortnight for three months. Mr. Wheeler considered this case an ideal one for operation for the following reasons:—(1) Previous tappings and laparotomy failed to give relief; (2) progressive emaciation and the appearance of slight jaundice was a warning against further delay; (3) the exploratory laparotomy revealed an attempt by Nature to anticipate the operation by the formation of adhesions; (4) the liver was enlarged, not atrophied, and therefore sufficient liver cells remained to carry on life; (5) there was an absence of an cardiac or renal complication. The great number of successful cases recently published were referred to, and the absence of the true "hob-nailed" liver and of an alcoholic history in so many cases commented upon. Mr. Wheeler considered that the efficacy of the operation was no longer in doubt.

Mr. **Haughton** said his experience of the operation was limited to two cases, which he described.

Mr. R. C. B. **Maunsell** quoted a case in which the operation had proved unsuccessful, in which a markedly cirrhotic kidney was found at the post-mortem.

Mr. **Benson** asked if there was any cirrhotic condition in any other part of the patient's body, as he had seen a case of a lady who had cirrhosis of the lung eight or ten years previous to the condition of the liver coming on. He thought it might add to the patient's comfort if he were tapped to get rid of the fluid that still remained.

Mr. **Stoney** and the **Chairman** also recalled cases of the operation.

Mr. **Wheeler**, in reply, said the patient had nothing in the way of cirrhosis in any other organs, but the last time his urine was examined it showed signs as if he was getting cirrhosis of the kidneys. He was not inclined to do anything more in the case as long as the man remained in his present condition. The fluid still remaining was the same in amount as it was at the time of the operation.

Mr. **Seton Pringle** exhibited a case of mucous colitis in which he had performed appendicostomy some months ago. The patient, a strong labouring man, with no sign of neurosis about him, sought treatment some two years ago for an uneasy burning sensation in the lower bowel and rectum, some pruritus ani, and the passage of a quantity of mucus in the stools. He was found to have hæmorrhoids, and these were removed by operation, but he returned some two months later worse than ever, and now the whole motion was often composed of cylinders of mucus. A course of treatment, consisting in daily irrigation of the large bowel with astringents and antiseptics, was then commenced, and persisted in for months, the patient at the same time being dieted and stomach sedatives, etc., given by mouth. As the treatment resulted in no improvement, Mr. Pringle performed appendicostomy last June in order to enable the whole large intestine to be systematically washed out. After giving a short history of this operation and describing its performance, Mr. Pringle pointed out that many cases of cure of mucous colitis by its aid had been reported, and so far no failures. Since last June the patient has washed out his own colon daily with various antiseptics, and latterly has been using argyrol 1 in 1,000 in the morning and normal saline solution at night, but Mr. Pringle regretted to have to report that the condition was in no way ameliorated, and he regards the treatment in this case as a complete failure. In conclusion, he called attention to the fact that the bowel had been examined carefully with the electric sigmoidoscope, and no gross lesion found, so that this is apparently a true case of mucous colitis, and not one of those cases of ulceration, kinking or growth which often so closely simulates this disease.

Mr. **MAUNSELL** said he considered the operation a most useful one. He suggested that if the medical treatment did not cure the patient, an ileo-sigmoidostomy might be successful, in which case the excluded piece of gut could be resected subsequently.

Mr. **BENSON** thought ipecacuanha might be tried.

The **SECRETARY** thought that, notwithstanding recorded cases, the operation was not a very successful one in cases of mucous colitis.

Dr. **STEVENSON** asked if any difficulty was experienced in keeping the aperture from closing, and whether the catheter was kept in the whole time.

Dr. **PUGIN MELDON** said that a weak solution of peroxide of hydrogen would clear away any foreign matter in the intestines; mixed with borax and bicarbonate of soda it might do some good.

Mr. **HAUGHTON** instanced a case of operation for ventral hernia which caused the disappearance of colitis that had been treated for a long time medically without success, and he raised the question as to whether Mr. Pringle had satisfied himself that there was no reflex cause for the disease in this case.

Mr. **PRINGLE**, in reply, said he would seriously consider the question of further operation if the suggested medical treatment proved of no avail.

Mr. **MAUNSELL** presented the case of an elderly man on whom he had operated for a carcinoma of the floor of the mouth. By the time the patient presented himself for treatment the growth had involved the tongue, and was extensively adherent to the jaw. The operation consisted of removal of half the tongue and a portion of the jaw, extending from the neighbourhood of the middle line to the last molar tooth. At a subsequent date the lymphatic glands on the same side of the neck were exposed, from the angle of the jaw to the clavicle, and removed. At the latter operation very considerable trouble arose in connection with the taking of the anæsthetic, probably due to the removal of the levators of the larynx at the previous operation.

The **CHAIRMAN** said there was no doubt that the probability of permanent benefit from operation for cancer of the tongue was not at all great, particularly in such a case as that before them. He expected that Mr. Maunsell's idea was to make the man's life more endurable, supposing that glandular recurrence came on after the removal of the disease in the mouth. In operating on parts far back in the mouth he recommended the performance of a preliminary laryngotomy. He thought it enabled them to work easier than where the patient had to breathe through the mouth. In a recent case, in which he had performed a preliminary laryngotomy, he found there was no anxiety about the hæmorrhage. Although Professor Kocher's recent method was only a modification of an old method, he considered it a great advance.

ULSTER MEDICAL SOCIETY.

CLINICAL MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST, ON DEC. 12TH.

The President, Dr. **JOHN McCAW**, in the Chair.

COLONEL J. R. DODD, F.R.C.S., and Captain E. P. Connolly were elected Fellows of the Society, and Drs. S. R. Hunter, Foster Coates, and R. Jamison were elected Members.

Dr. **ALLEN** showed a case of coloboma of the iris and choroid.

Mr. **ROBERT CAMPBELL** showed a case of malformation of one great toe.

Dr. **A. B. MITCHELL** showed a boy of 8 suffering from an obscure nerve lesion of several months duration. There was a most peculiar gait and staggering movements, but no loss of power. There had been optic neuritis, and there was now atrophy. On the whole the general opinion was that the case was one of cerebellar tumour.

Dr. **CECIL SHAW** showed a child of 9 suffering from a peculiar thickening or chemosis of the conjunctiva in one eye This was situated high up under the upper lid, and had persisted unchanged for some three months in spite of various local applications. Dr. Cecil Shaw also showed a girl of 15 with extensive ulceration and cicatrization of the pharynx and soft palate of four years' duration. No history of syphilis in the family could be found, nor any other signs of syphilis in the girl.

Dr. **McKISACK** showed a case of exophthalmic goitre in a young woman. As her symptoms grew steadily worse during two months of medical treatment in hospital, surgical interference was decided upon, and half the gland was removed by Mr. Robert Campbell, since when there had been a distinct improvement.

Dr. **RANKIN** showed a series of cases undergoing X-ray treatment for lupus and epithelioma.

Dr. **JOHN McCAW** showed 4 cases, which will be found in another column under heading "Clinical Records."

Dr. **DEMPSEY** showed a tumour weighing 27 lbs., which he had removed from a woman lately.

Professor **SYMMERS** and Dr. **A. E. MITCHELL** exhibited specimens of primary sarcoma of the pancreas, and secondary deposits in the left ovary, liver, and right lung.

Mr. **HANNA** showed the brain of a child who had been submitted to a radical mastoid operation, and afterwards developed purulent cavernous sinus thrombosis. No abscess was found in the brain.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, DEC. 12TH, 1907.

The President, Mr. R. **MARCUS GUNN**, in the Chair.

THE following is an abstract of Mr. Nettleship's paper on

SOME CASES POSSIBLY ALLIED TO TAY-SACH'S INFANTILE RETINITIS.

It was suggested that the amaurotic family idiocy of Waren Tay and Sachs, although usually fatal in infancy, and limited to children of pure Jewish origin, might sometimes be milder, allowing the child to live several years, or even to grow up, and that many families of "Gentiles" contained more or less Jewish blood. The author thought that cases such as those described by Dr. F. E. Batten, Mr. Mayou, and others, in which amblyopia, with slight changes in the macular region, came on a few years after birth, and was sometimes associated with progressive cerebral degeneration, might be mild examples of Tay's disease. Also that the same might be true of certain cases of amblyopia counted as congenital, in which there was central defect in the field, and sometimes nervous or mental failure, but no tendency to early death. In the best marked of these cases there was colour-blindness, often total and complete, and day-blindness, but in the less severe ones there might be no colour defect and no dislike of strong light. All these forms of non-fatal amblyopia were, like Tay's disease, liable to run in families.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Dec. 15th, 1907.

URÆMIA.

THE clinical forms of uræmia are very varied and differ according to individual cases, yet there is a certain number of symptoms which are common to all varieties.

The quantity of urine, for instance, is always diminished at the period of uræmic accidents, but it varies in degree according to the cause of the uræmia. In uræmia following acute or subacute nephritis (parenchymatous nephritis) oliguria is very pronounced even to anuria. On the other hand where the subject suffers from interstitial nephritis the quantity of urine may be almost normal, considering that during the course of the malady and before uræmic symptoms had set in, the patient urinated two or three quarts daily.

Parallel to oliguria, urea diminishes considerably and frequently albumin increases, but not constantly.

Generally speaking, the temperature falls progressively below the normal, especially where the malady is approaching a fatal termination.

Arterial hypertension accompanies constantly uræmia and the pulse becomes slower; this bradycardia is nearly always observed in the chronic forms.

In certain cases the sight is affected with slight amblyopia or even complete amaurosis. The principal characters of this last accident lie in the fact that it is independent of any ocular lesion, appears suddenly and is always transitory, disappearing after the attack.

Of all the nervous symptoms, headache is the most important and the most frequent, resembling frequently migraine. The headaches, says M. Chauffard, are intense, continual, or intermittent, accompanied by vertigo and inaptitude for all intellectual work.

Among the cutaneous troubles observed in the course of uræmia may be mentioned pruritis, eczema, urticaria, erythema, and in some case a kind of frost produced by urea covers the skin under the form of small white crystalline flakes; it is always a grave sign, and is observed only in the last stages of uræmia.

The above symptoms are general to all forms of uræmia, but when the acute symptoms set in they affect chiefly the nervous system, the respiratory apparatus, or the digestive tract.

The nervous troubles consist in convulsions, delirium, and coma, which is the final stage.

Convulsions can complicate all varieties of nephritis, but they are especially frequent in nephritis following scarlatina, and principally in children and in parturient women (eclampsia).

Delirium is observed generally, according to Dieulafoy, in persons predisposed to mental disturbance, either from alcoholism or from some hereditary taint.

Coma is the natural termination of all other nervous forms of uræmia. In some cases it sets in gradually, preceded for several days with a sensation of heaviness in the head, the patient becoming apathetic and somnolent.

In other circumstances it strikes the patient suddenly; he falls and remains unconscious. This apoplectic attack has been studied by Raymond; it generally affects persons of a certain age suffering from chronic nephritis which had remained latent and only brought into evidence by the attack. The patient succumbs almost immediately; it is an important cause of sudden death. Brouardel used to say that sudden deaths from kidney affection were much more frequent than from any other cause.

The respiratory symptoms of uræmia are dyspnœa *sine materia* or that associated with, and more or less dependent on, bronchitis and pulmonary congestion.

The former may consist in a simple sensation of oppression, or it may be acute resembling attacks of asthma when the patient is seized with anguish and a sensation of impending death. The respiration of Cheyne-Stokes is observed in the last period of chronic nephritis, and constitutes a symptom of great gravity.

As a general rule, the existence of uræmia should be suspected in every patient of over 40 years of age who suffers from dyspnœa.

Lasègue describes three types of bronchitis due to albuminuria.

In the first, the patient complains of intense dyspnœa, coming on in paroxysms, and especially at night; it is due to an attack of pulmonary œdema.

The second type is characterised by dyspnœa, coming on suddenly; cough is frequent, and expectoration is mucous; crepitating râles are perceived by auscultation.

In the third form bronchitis is general, cough frequent, and expectoration abundant

Besides these forms there remains acute œdema of the lungs. Suddenly, and generally at night, the patient is seized with acute dyspnœa, the face is cyanosed, cold sweats cover the body, and expectoration, spumous and sanguinolent, is exceedingly abundant. Fine râles, which invade rapidly all the chest, like the incoming tide, according to the expression of Renaut, are heard by auscultation. The pulse becomes thready, the heart becomes weakened, and the patient succumbs rapidly unless he is bled promptly.

The digestive symptoms of uræmia consist of furred tongue, vomiting, and sometimes diarrhœa. Vomiting is one of the most constant signs; the patient rejects at first food, and afterwards has bile and mucus. The amount of liquid rejected in the 24 hours is sometimes very considerable. Chronic uræmia is observed chiefly in persons over 50 years of age, already suffering from chronic or instertitial nephritis. The premonitory symptoms are those already mentioned—headache, intellectual apathy, insomnia, troubles in the respiratory rhythm, attacks of nocturnal dyspnœa. According to Fournier, inappetence, vomiting, diarrhœa, succeeding to a prolonged period of constipation, are the constant symptoms of chronic uræmia.

Acute uræmia is met with chiefly in the course of acute nephritis, and particularly in children. It is also observed in individuals who have suffered from latent chronic nephritis, which was suddenly manifested by uræmic accidents.

Acute uræmia frequently has for its only symptom sudden coma (apoplexy). Individuals, says M. Castaigne, who in the midst of their occupations—frequently even while at table or immediately after—fall suddenly and die in a few minutes. Such cases are frequently observed in asylums for the aged.

The treatment general to all forms of uræmia is that of nephritis. The patient, who should be recommended to avoid all cold or brusque changes in temperature, is put on milk, given drastic purgatives, diuretics, intestinal antiseptics (benzo-naphtol), and enemas of cold water. Such is the treatment of the attenuated form of uræmia.

In the graver and complicated forms the treatment should be more energetic. Blood-letting for coma, eclampsia, and acute œdema of the lungs, inhalations of oxygen gas, small doses of morphia, subcutaneously if the dynspnœa is not relieved, or inhalations of nitrite of amyl. Pills of ipecacuanha (1 grain), and opium (1-10th grain) may be given until nausea sets in.

The vomiting and diarrhœa of uræmic persons should, in general, be respected, as they remove the toxines which the kidney cannot eliminate. Where it is judged necessary to arrest one and the other, it is generally sufficient to place the patient on the hydric diet (a quart and a half of boiled water daily) for two or three days.

GERMANY.

Berlin, Dec 15th 1907.

The Prussian Minister for Medical Affairs has recently issued an ordinance directing midwives to use creosol soap as a disinfectant in place of lysol, the one in use before this.

The creosol soap is directed to be made in the following manner: 60 parts of linseed oil are to be heated in a water bath in a roomy, loosely closed vessel; then is to be added under agitation the following solution—viz., 12 parts of potassium hydroxyde in 30 parts of water and 12 of rectified spirit. The mixture thus formed is to be heated to complete saponification, and when this has taken place 100 parts of creosol of a boiling point of 199° to 204° C. are to be added. The resulting liquid must be clear, and of a yellowish brown colour. It is to be marked "For external use only." It must be used in a 1 per cent. solution only, and must be prepared for use in the following manner: A litre of lukewarm water to be poured into a clean dish or bottle, and 10 grammes of the creosol soap are then to be added under agitation. It must never be prepared for use in a tinned or painted vessel.

The Sleep of School Children.

The School Physician, Dr. J. Bernhard, has recently issued a report on this subject after an examination of 6,551 children. He reports that for all ages from 7 to 15 years of age the time the children get for sleep is far behind their physiological requirements. This shortage of sleep he attributes to the work the children are required to do at home, such as carrying out parcels, street trading, etc. Only one-third of the children have a bed each; the rest sleep two or three, or even four, in a bed.

At the Hufeland Society Hr. Ewald showed the Reactions of the Bence-Jones' Albuminous Bodies, which are derivatives of albuminosis. In very slightly warmed urine a cloudiness takes place at a temperature of 37° to 40° C. This becomes stronger on further heating. By still further heating, however, the urine becomes clear again. The process was the reverse, therefore, of that which took place with albumen.

The patient from whom the urine was obtained was a man, æt. 56, who came from Russia, and presented the following symptoms: He had suffered for years from mitral insufficiency. He had complained lately of pains over the region of the left breast, great weakness with distension of the abdomen. There were no œdematous swellings, and no other noticeable disturbances. The abdomen was distended in a peculiar manner, just like an india-rubber cushion. A tumour the size of a small apple could be felt between the umbilicus and the left ribs. Tapping of the sternum, tibia or bones of the arm caused no pain. There was complete absence of free and combined hydrochloric acid in the stomach contents. Digestion imperfect. In the urine, which was of a sp. gr. of 1,010, were the above-mentioned albuminous bodies precipitated by ricinic acid, and to an extent of 1 to 3 per cent. The fundus oculi was free. There were no typical changes whatever in the blood; with the exception of a small increase of the lymphocytes the blood was quite normal.

The diagnosis was based on the urine alone. The appearance of Bence-Jones' albuminous bodies had been associated with various diseases, all of them connected with the bony system. According to Ellinger, they were cases of chondro- or lymphosarcoma, which appeared in a multiple form within the bones, but which were not visible outwardly. According to the speaker, two forms must be distinguished, the one presenting the form of chronic osteomalacia, in which easily palpable bony changes were present; the other ran its course with symptoms of gradually increasing weakness. The case shown belonged to this category. The condition of the urine was in favour of this. Cases of true Bence-Jones' albumosuria were very rare. The lymphosarcomata developed either in the bone marrow or in the abdomen. There was no demonstrable ascites, but some fluid was certainly present in the abdomen. During the last few days the patient had complained of pain in his left arm, and had vomited several times.

The treatment of such cases was indicated pretty plainly: injections of atoxyl, and Röntgen-ray treatment over the spleen every second day. The results were apparently favourable. The number of lymphocytes had diminished, but this might be accidental.

Hr. Benda communicated a short note on

Periarteritis Nodosa and Periarteritis Syphilitica.

Attention was first drawn to these subjects in 1866 by Kussmaul and Maier. The clinical features of the affections were obscure. The symptoms were those of a labourer who had previously been healthy, and who had gradually faded away with marasmus. At the autopsy numerous small vesicles were found on small vessels and widely distributed over the internal organs. On closer examination small aneurysms were found, in which the external layers of the vessels participated. Up to 1904 17 such cases had been collected. Three publications on the subject had appeared during the past three years. The pathological conditions were the same in all cases—viz., a widespread aneurysmosis of the smaller arteries passing on to the larger ones. There was a tendency to thrombosis, and to a change in the other organs. The cerebral arteries had escaped attack except in one instance; all the other arteries were liable to become implicated. In two cases observed by the speaker a diagnosis of chronic nephritis had been made. In one case there was hypertrophy of the left ventricle, emphysema and symptoms of stasis; in the other cirrhosis of the liver. In this case death was brought about by hæmorrhage into the abdominal cavity. The diagnosis had never been determined with certainty during life, and only once had a microscopical examination confirmed the suspicion.

AUSTRIA.

Vienna, Dec. 15th, 1907.

Angioma Arteriale Racemosum.

Clairmont reported the history of a case on which he operated for a racemose angioma on the head. He commenced the operation by incising the circumference of the tumour, and then dissected the vascular swelling from before backwards. Fourteen days after the operation the patient took an epileptic fit; the fits have repeated themselves since that time. They seem to be due to the distension of the intra-cranial vessels from the collateral circulation.

Radio-Therapy of the Ischias.

Freund exhibited a case of ischial neuralgia of a persistent character that resisted all sedative drugs, but yielded to irradiation. The sacrum and foramina were exposed only twice to the rays, when comfort was obtained, and after the sixth application the pain disappeared completely. He recorded the history of other five similar cases, with equally beneficial results. He thinks these happy results are obtained by the Röntgen rays dilating the vessels and relieving the contractile fibres around the nerve.

Relation Between Lymph and Glycosuria.

Biedl gave the Association a lengthy demonstration of the close relationship between glycosuria and lymph circulation by cutting of the chylous and lymph currents by ligature on the ductus thoracica, which produced glycosuria. From this he concludes that there is a principle in the lymph that has the power of transforming the saccharine principle into a glucoside, which is eliminated in the form of glycosuria. This substance in the lymph is the product of some internal organ, and has the power of regulating the transformation in the organism.

Cranio-Plastic Operations.

Lotheissen next showed the members a child over two years old with a defect in the cranial bones, measuring 7 by 5 centimetres. The history of this defect led to the conclusion that it was the result of a traumatic cephalic hydrocele. He first commenced by a periosteal flap from bone according to the Muller-Konig method, which did not succeed. He next adopted the Hacker-Duraate method, which is to induce a subaponeurotic flap to take the place of the dura mater, but with no better result. In hopeless despair he resorted to transplanting cartilage from bone, but with no more success.

Fleishmann thought this was a case where the dentine was absent as in rhachitis. In this disease the calcareous changes take place early and linger long.

Tænia Cucumerina.

Koenigstein showed a child whom he was treating for tænia. For two months past the child had been passing segments which were diagnosed as cucumerina. He had passed into the stomach by means of a tube ½ gramme of extract filicis maris in a syrup of peppermint, but the half of it was soon after vomited. A metheglin or hydromel was next prepared and administered, bringing away three of the worms entire, which confirmed the diagnosis.

According to statistics about 50 per cent. of these cases arise from children playing with cats, but in this case no direct contact with either cat or dog could be traced. Is it possible that the infection was carried by external parasites such as fleas, which have been proved to carry one of the tænia's transitory forms?

Pemphigus Contagiosus.

Koenigstein presented another case, a child, six months old, with large circular and poligonal markings on the body with different colours. From its age he thought the bullæ could not be pemphigus neonatorum, but rather Escherich's pemphigus infantum, or more generally speaking pemphigus contagiousum from the well-known infectious nature of the disease. Nurses and mothers convey the infection easily. In the Leipzig Children's Hospital in 18 months out of 400 children 98 were infected with the disease. Koch records 30 children in one neighbourhood where the infection was undoubted. The bacterium found is a staphylococcus pyogenes, which when cultivated and inoculated produces the disease.

Clinically, as well as anatomically, this disease differs from the pemphigus chronicus of the adult. It differs from impetigo contagiosa from its efflorescence, rapid formation of pus, and from its not attacking the face, soles of feet, and palms of hands.

HUNGARY.

Budapest, Dec. 15, 1907.

At the recent meeting of the Budapest Interhospital Association, Dr. Rozsa presented a patient with

Stricture of the Œsophagus.

The patient began to have difficulty in swallowing, with regurgitation of food, about one year ago, necessitating eventually a gastrostomy. This operation was done in the St. Rochus Hospital, with apparently a good result. An œsophageal bougie could not be passed beyond the level of the junction of the manubrium with the gladiolus. He had the patient swallow a large amount of bismuth, and then made a radiograph, which showed the obstruction, and to the left of it a tumour. The obstruction was a saccular one. After the passage of steel sounds, the man was able to swallow milk, but at present was feeding himself through the gastrostomy wound. This case showed the value of X-ray and bismuth for diagnosing these conditions.

Chemistry of Chronic Nephritis.

Dr. Kovàcs concludes, from the chemical examination of the blood, kidneys, and various other organs, particularly with reference to the chlorides, as follows: In health the amount of chloride of sodium in the kidneys generally exceeds that in the blood and the other organs. In a large number of cases of nephritis the difference is still more marked, but exceptions are common, especially in the early stages. The amount of salt in the blood and tissues in nephritis is usually above normal; yet there are many cases where the opposite holds, despite the presence of œdema, albuminuric retinitis, and uræmia. The percentage of chlorides found in the pericardial, pleural and peritoneal fluids of nephritis is not constant. Since higher figures were obtained with the transudates of other conditions, it is improper to conclude that transudation in nephritis is a result of retention of salt. There can be no question, however, that there is a decided retention in the kidney of chlorides, sodium potassium, calcium and magnesium. In the early stages of nephritis the blood and tissues contain less water and more solid residue, but in the later stages this is no longer constant.

The Origin of Acute Miliary Tuberculosis.

Dr. Kuthy carefully investigated all the autopsy records of four years in order to decide how a local tuberculous process generally becomes disseminated. In 95 per cent. of the cases tubercles of the vessels or of the thoracic duct were found which had permitted the bacilli to gain the blood-stream. It is well known that Rippert strongly opposes this theory, since he has frequently hunted in vain for tubercles large enough in the walls of the vessels in his cases to account for the large number of metastatic deposits in the body. Furthermore, he states that the focus is not always ulcerated, and that the different size of the tubercles, especially in the lung, argues for a different age. It seems more probable to him that an active proliferation occurs into the capillaries, and that the blood is constantly contaminated from this source. The author states, however, that the capillary focus is generally inadequate, and that it is often present even where there are no miliary tubercles is due to the fact that the same number of bacilli is not transported to all parts of the body, and that different tissues do not permit an equal development.

Pyramidon in Tuberculosis.

In the internal section of the St. John Hospital in Budapest the fever of consumptives is managed as follows: As soon as the patients reach the hospital, they are put to bed. If the fever does not disappear spontaneously after five to six days, he receives 20 centigrammes of pyramidon in half a glass of water, which he is instructed to swallow slowly during half an hour after his mid-day meal. If effective the dose may be diminished after several days, while sometimes it may be necessary to give more. With inverse type of fever, the drug must be administered during the early morning hours. Bad after-effects are rare, and never amount to more than urticaria, profuse perspiration, or darkened urine. A marked improvement will be noticed in the condition of the patients as soon as the fever has disappeared; they will increase in weight rapidly, and the process in the lungs will tend to recede.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

Public Health.—The Public Health Committee of the Corporation have submitted to Mr. Birrell the following points which they wish included in the Bill he is expected to introduce next Session:—(1) To establish municipal dispensaries for the treatment of tuberculosis; (2) medical examination of school children, as in England; (3) to obtain control of all milk supplies, whether coming within their district or not, including the inspection of dairies, and cattle in them; (4) to establish and operate plant for the sterilisation and pasteurisation of milk, including purchases and sales; (5) to insure their sanitary officers against sickness and death from infectious disease; (6) to compensate persons stopping employment on account of infectious disease; (7) to provide for the appointment of a deputy medical superintendent officer of health in the absence or illness of the medical officer; (8) to require that all district medical officers of health should be qualified by the possession of a diploma in sanitary science; (9) the Committee are of opinion that the milk provisions, including the ice-cream clause of the Public Health Amendment Act Bill, which were struck out when the Bill was before Parliament last Session, should be reintroduced; also that power should be given them to maintain persons removed from their homes to temporary places while their homes were being disinfected. As will be seen, these recommendations open up many broad and controversial questions, and, if adopted by Mr. Birrell, would give new and far-reaching powers to the Public Health authorities, which might easily be abused. Their adoption *in toto* is, however, far from likely.

LETTERS TO THE EDITOR.

"THE BROWN DOG" INCIDENT.

To the Editor of The Medical Press and Circular.

Sir,—There is no analogy between the slaughter of a bullock in an abattoir and the death of the "Brown Dog," for the simple reason that no law exists, that I am aware of, as to the time or manner in which a bullock should be killed. Had we such a law, and the slaughterer treated it with contempt, no doubt he would be prosecuted, and a well-merited punishment result. There is such a law for the victims of vivisection; allow me to repeat it:—"The animal must be killed immediately the object of the experiment is obtained." Out of the vivisectors' own mouths we know this law was flouted, for the object was obtained after the second operation, and no juggling with anæsthetics can make the third operation other than a transgression of this law, and therefore illegal. Had the Home Office done its duty, and not been a mere tool in the hands of the vivisectors, their prosecution ought to have followed.

I am, Sir, yours truly,

Dec. 15th, 1907. Frances E. White.

To the Editor of The Medical Press and Circular.

Sir,—Your correspondent, Frances E. White, is perfectly correct. On the evidence of Messrs. Starling and Bayliss, the brown dog was vivisected three times. For some two months it was kept without exercise, and in a more or less mangled condition, in a cage. In contravention of humanitarian provisions in the Act, Professor Starling, instead of its being killed "in a perfectly legal and proper manner," handed over this dog to Mr. Bayliss, who in his turn failed to see that the dog was killed as required by the Act; and, as far as the evidence at the trial shows, the sworn testimony left the manner of the dog's death a mystery, the evidence being contradictory and unsatisfactory. You, Sir, however, now tell us that when you wrote that the dog "was destroyed in a perfectly legal and regular manner," you simply spoke of the death of the dog. Let us have none of that juggling which you dislike so much. Will you, as you know, tell me (what could not be discovered at the trial) when the dog was actually killed, by what means, and by whom?

I am expressing no opinion as to the advisability of the erection of the statue, or the taste displayed by the inscription thereon. The latter may or may not be "libellous." But if "the greater the truth, the greater the libel" holds good, and this is a libel, it is about as big a libel as one can think of. But you, Sir, posing as a champion of legality at times, ask "would the anti-vivisectionists have preferred another dog to have been used instead?" Why, most certainly, yes! And for two reasons—first, because, though we desire to repeal the Act licensing vivisection, we desire, in spite of the example of certain "highest authorities" (as Sir William Church would say) that an Act should be obeyed and its provisions respected; secondly, a fresh dog would in any case be preferable to the lengthened spinning out of the doing to death of this brown dog. As to serums, I am only a layman, but for years I have studied the *ipse dixits* of responsible practitioners and experimenters, and I know something of their own accounts of results achieved in cases of diphtheria, with and without its use. I think you will easily find some dozen high authorities who have produced excellent cures without the results of animal experimentation in diphtheritic cases? I have no time to supply you with information in detail, and which you can easily discover yourself. One would like to know your opinion of medical students who behave as some did at Acton, and used stink-pots for ladies' annoyance? Hoping you will give us your exclusive knowledge of the brown dog's death simply and clearly with no juggling, so very distasteful to us all, and I propose to trouble you no further.

Yours, etc.,
GEORGE W. F. ROBBINS.

The Battersea General Hospital
(The Anti-Vivisection Hospital), London, S.W.
Dec. 12th, 1907.

[We have published Mr. Robbins' letter in full, except for one sentence consisting simply of abuse which we thought better to delete. Mr. Robbins admits he is a mere layman: we therefore feel absolved from arguing technical medical points with him. The value of anti-toxin in diphtheria, of course, is admitted by every physician experienced in fevers. If Mr. Robbins will do us the compliment of reading THE MEDICAL PRESS AND CIRCULAR for the last few weeks, and also for this, he will ascertain our opinion about the student disturbances. With regard to the dog's death, we repeat that it was destroyed in a "perfectly legal and proper manner." If anti-vivisectionists wish to labour the point of the demonstration being given on a dog which was under an anæsthetic used for a previous operation, there was no doubt, on the face of it, a technical breach of the Home Office regulations pertaining to that particular certificate. Nothing but disingenuousness could distort it into anything worse. Being fond of dogs ourselves, we would like as few to be used for experimental purposes as need be. When an animal is under an anæsthetic, it can make no difference if two operations lasting, say, half-an-hour each, are performed, or one lasting an hour. If Mr. Robbins prefers two dogs to be used when one would do, to our mind that shows that he cares more for "getting at" his opponents than for animals' lives. The fact of the matter is, neither operation killed the dog in question, but it was subsequently destroyed in the adjoining room after the demonstration was over. To say that it was "done to death" is equivalent to a charge of improper killing.—ED. M. P. AND C.]

THE PROFESSION AND THE PUBLIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is remarkable that no fewer than five letters in your correspondence pages of this week have direct or indirect bearing upon the question of the present position of the profession in relation to the public. First there are the anti-vivisection contributions on the "Brown Dog" disturbances. There cannot be any doubt that the students' demonstrations merely express, whether foolishly or not, the indignation which every member of the profession must feel with regard to the torrent of calumny to which medical men are being systematically treated by anti-vivisection fanatics and their blind followers. These fanatics, although sometimes disclaiming the intention, are virtually engaged in a well-organised campaign carried on by active agents throughout the length and breadth of the land, in which the main argument of speakers and writers virtually holds up the whole profession to execration as the supporters of "vivisectors," "anti-human wretches," who devote their lives to the infliction of unspeakable torture upon poor dumb brutes, well knowing that the results must be of more than doubtful value. They often charge the bulk of doctors with callousness and cruelty due to the training which they imagine students go through. The anti-vaccinationists are carrying on another campaign hardly less widely and actively. These fanatics charge the whole profession—those who duties do not include vaccination as well as those who are called upon to perform the operation—with carrying on for paltry gain a gigantic conspiracy through which a loathsome poison is disseminated among the people, including their own children, whom they sacrifice to cloak their hypocrisy. The other letters which you print to-day on "The Midwives Act," "Proprietary Medicines," "Medical Law," and "Quack Methods," simply illustrate from other various standpoints the position of degradation and political impotence in which the profession stands. Vast masses of the public have become imbued with ideas which make them look upon the profession with suspicion and dislike, if not with hatred.

Is it necessary that, to use the vulgar phrase, the profession should take all this lying down? I do not know, but this I do know, that if the present state of things be allowed to continue it must become more and more difficult, as time goes on, to bring into the profession men of honour and of self-respect. I do not think I can be exceptional, and in my own case I have persuaded my son, a boy of uncommon talent with a bent towards science and to a career as a medical practitioner, to abandon his intention in favour of some avocation less likely to lead to humiliation and unhappiness. If the position of the profession cannot be improved it will soon become impossible for anyone to succeed in it from the worldly point of view unless he lower himself to the intellectual level of his patients, make up his mind to pander to popular prejudices, and deliberately adopt the principles and practices of dishonourable charlatanism. I enclose my card, and subscribe myself,

Yours, etc.,
ANOTHER OBSCURE PRACTITIONER.

December 12th, 1907.

HUMANITARIAN ABATTOIRS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The City Corporation are to be congratulated upon having at last taken action in the matter of slaughterhouse reform, and we note with satisfaction the inauguration of their commodious abattoir at Islington, in which up-to-date and humane methods of killing will be employed.

The Humanitarian League has been working for this reform for years, and is at the present time urging upon the London County Council the need of establishing abattoirs in the place of the many private slaughterhouses which exist within the metropolitan district. The advantages of public over private slaughterhouses, both for hygienic reasons and humane, have been repeatedly demonstrated by recognised authorities, official and otherwise. Many years ago Sir Richard Thorne Thorne, Medical Officer of the Local Government Board, recommended the abolition of private slaughterhouses and the substitution of well-ordered abattoirs in which it would be possible to enforce an efficient scrutiny as to the fitness of the meat for human consumption. The same conclusion was arrived at in the Report of the Royal Commission on Tuberculosis in 1898; also in that of the Public Health Committee of the L.C.C. in 1899, and at a conference of sanitary authorities held at the County Hall on July 7th, 1904, on the subject of the Administration of the Public Health (London) Act.

In view of this, and of the fact that municipal slaughterhouses have been established in a number of provincial towns in many parts of the United Kingdom, as well as on the Continent, there is the more reason why the L.C.C. should no longer postpone the carrying out of its own Public Health Committee's recommendation, to the effect that, "as a first step towards ensuring the proper inspection of meat, private slaughterhouses should cease to exist in London."

I am, Sir, yours truly,
JOSEPH COLLINSON.
Humanitarian League, 53, Chancery Lane, W.C.,
November 13th, 1907.

THE THERAPEUTICAL SOCIETY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, Dr. Burnet, refers to some rule of the Therapeutical Society hindering open discussion. There is no rule, however, which relates to the publication of any of its proceedings. The restrictions which were imposed by the then Council have been removed by their departure into the calm refuge of the Royal Society of Medicine. I imagine the delay in resuming meetings is due to want of a secretary. Do you happen to know of one?

I am, Sir, yours truly,
A FELLOW.
December 12th, 1907.

THE NATURE OF THE SOUL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to your article (December 11th) mentioning my appearance in *Black and White*, I surely need hardly say that it was not there either directly or indirectly through any of the few business qualities I possess. The exciting cause may be traced to a paper on "The Psychology of Crime," which I read recently before an *élite* medical audience, at which some distinguished laymen were also present.

I shall feel obliged if you will review the paper next month, when it appears in the *Journal of Mental Science*, and devote a little space to the criminal question in your valuable and influential columns.

I am, Sir, yours truly,
22, Langham Street, W., ALBERT WILSON.
December 16th, 1907.

OBITUARY.

THOMAS GLASBROOK DAVIES, L.R.C.P., L.R.C.S.ED., L.F.P.S.GLASG.

WE regret to record the unexpected death of Dr. T. Glasbrook Davies, of Manselton. Dr. Davies was only taken ill last Thursday, but somewhat serious symptoms showed themselves on Saturday night, and it was seen that he had pneumonia. Notwithstanding his illness, Dr. Davies insisted upon attending to a young man who was injured last Sunday morning, and this possibly aggravated his case, as the weather was very bad. He succumbed at his residence in Courtenay Street, Dr. Davies was only 39 years of age, and was exceedingly popular, and great sympathy is felt with his bereaved widow and relatives. It was only about two years ago that he married a daughter of Mr. David Glasbrook, Morriston.

LITERARY NOTES.

MR. CORNWALL ROUND has published a third edition of his little tract, "Self-Synthesis a Means to Perpetual Life" (London: Simpkin, Marshall and Co., 1907, pp. 32, price 1s.), in which we have found much to interest us. The author discusses the influence of the sub-conscious on the conscious mind, or, as he prefers, the subjective on the objective mind, and shows to what an extent the life and conduct may be altered by self-suggestion. He carries his views to an extreme point in maintaining that death is merely the result of suggestion received from others, and that therefore it may be avoided by a stronger self-suggestion. The author gives examples of some of the ways by which self-suggestion may be practised.

⁂

THE Caxton Publishing Company announce a work in the press, an "Atlas of Obstetrics," to which the stereoscopic method has been applied throughout. The work is edited by Dr. Barbour Simpson and Mr. Edward Burnet, M.B., Ch.B., of Edinburgh. The work will be on the same lines as "The Edinburgh Stereoscopic Atlas of Anatomy." Its aim is to provide a permanent record of things "as they are seen"; to supply a complete set of types of normal and abnormal pelves; and to illustrate the mechanism of labour in a manner unapproached by any other method of demonstration. Professor Sir J. Halliday Croom contributes a preface to the work.

⁂

WE have received a "Household Emergency and Reference Chart" from Major R. J. Blackham, R.A.M.C. This chart is designed to convey, in a graphic manner, practical directions for action in a variety of emergencies likely to occur in everyday life, and it gives us pleasure to say that the author has certainly fulfilled his object. The information is conveyed in language which cannot fail to be understood by any person of average intelligence, and this fact, of course, contributes greatly to the undoubted value of Major Blackham's scheme. While the chart has a wide field of applicability, we recommend it in particular to parents, school teachers, and to all, in fact, who have the care of children. It would be well if every household and school were provided with a copy.

REVIEWS OF BOOKS.

ON PNEUMONIA (a).

THIS small work is really the substance of clinical lectures and demonstrations delivered by the author at the West London Hospital to post-graduates. So much has been written on this subject that it is difficult to find anything new to say regarding it. Referring to the connection of pneumonia with influenza, Dr. Hood suggests that the attack may be of the nature of a lung paresis, and, judging from the physical symptoms, the state is one of rapid œdema or passive engorgement. He quotes actual cases bearing out his contention. The distinction between ordinary and influenzal pneumonia is that in the latter form asthenia and copious perspiration are more common, the range of temperature is not uniformly so high, and is far more irregular. The difficulties of diagnosis are very fully dealt with, and illustrative cases introduced.

As to treatment, there is no specific. Dr. Hood wisely insists on the necessity of abundance of pure, fresh air as an essential part of the treatment. Coal-tar compounds are condemned. He has a good deal to say regarding the treatment of fever, and mentions that pure, fresh air will often quickly influence the pyrexia in many cases. Tepid sponging is the best remedy against restlessness and insomnia. If drugs are needed chloralamide is one of the best. Sulphonal and veronal are often disappointing in their results in such cases. Dr. Hood has found digitalis to be of little service, but strychnine "is certainly one of the most useful drugs we possess," while oxygen is often a valuable adjunct to treatment. Those who have to treat pneumonia—and what general practitioner has not?—will find in Dr. Hood's teaching much that is practical and common-sense. It is thoroughly sound, and appeals at once to the reader. Many suggestions as to diagnosis will also be gleaned from this small volume, which we have perused with much interest and no little satisfaction.

(a) "Some of the Clinical Aspects of Pneumonia." By Donald W. C. Hood, C.V.O., M.D, Cantab, F.R.C.P. Lond.; Senior Physician to the West London Hospital. London: John Bale, Sons, and Danielsson, Ltd.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Remarks on the Theory of Chorioepithelioma.—Eden (*Journ. Obst. and Gyn.*, December, 1907).—After reviewing most of the literature on this subject, and giving notes of a case, the writer sums up the whole question as follows: Chorioepithelioma is a form of malignant growth which occurs in both sexes. It is very much more frequent in women than in men, and pregnancy is its most potent predisposing cause. In women it usually arises from fragments of chorionic tissue, normal or abnormal, which have been retained from a previous pregnancy. It may, however, occur in women independently of previous pregnancy, and in such cases its origin cannot at present be explained. In men it is generally, perhaps invariably, of teratomatous origin. F.

The Menstrual Function: Its Influence upon Chronic Inflammatory Conditions of the Appendix.—Reder (*Amer. Journ. Obst.*, November, 1907).—Why should the menstrual function provoke an attack of appendicitis? The menstrual function can only provoke an acute attack in an appendix that is chronically diseased. The menstrual function must be considered as an habitual functional hyperæmia, and as such must be looked upon as the causative factor. After a painstaking consideration of cases, I can state that only in the severest forms of adnexal disease can the inflammatory condition communicate itself to the appendix, and cause the primary acute attack. It is in the chronic form of appendicitis, be it a catarrhal or an interstitially diseased appendix, where a pelvic hyperæmia can arouse the dormancy of a smouldering appendix and provoke the clinical manifestations for acute attack. Why a smouldering appendix should show activity one, two, or three days before menstruation, and remain quiescent at other times, is a difficult matter to reason out satisfactorily. I have come to the conclusion that such an appendix can show activity independently of the menstrual function provided the proper conditions exist favourable to an attack. Why have not these patients suffered any acute attacks at a time when the menstrual function was not in evidence? Equilibration of the metabolic forces is essential to the maintenance of health. These women are in good health, and only at the time of their periods do they suffer from this abdominal pain. We must infer from this that there is a sufficient force of the element of health in the body to keep in check the microbic action of a diseased appendix. I assume that upon this principle it may be explained why acute attacks have not occurred in these women during their intermenstrual periods. On the other hand, at the time of menstruation, every woman suffers more or less from a systemic depression. Through anatomical channels and often through pathologic tissue changes; the appendix must share in the congested condition of the pelvic viscera, and such an influx of blood to a surrounding appendix is an incentive for bacterial activity. It could be expected that through the lowered vital resistance the obsonic power of the blood would be reduced, thereby favouring the pathogenic microbes harboured in the stagnant secretions in the lumen of a diseased appendix, or that through the lymph channels have found lodgment in the walls of the organ. F.

Phlebitis Following Abdominal Operations.—Pfaff (*Amer. Journ. of Obst.*, November, 1907).—After discussing the etiology of post-operative phlebitis, and stating it occurs in about 2 per cent. of cases, the writer, in conclusion, says it seems to him we are justified in accepting as facts:—(1) Many of these cases are simply extensive blood clots, without any true inflammation; (2) an abnormal plasticity of the blood must be present in order that thrombosis may be the result of surgical traumatism; (3) the clot generally receives a mild form of infection introduced into the wound at the time of the operation, and in turn an invasion of the vein wall results; (4) as stagnation is such an important element in the etiology, getting our patients up earlier will undoubtedly reduce the liability to thrombosis; (5) as an abnormally high degree of plasticity of the blood is essential in developing the disorder, the blood ought to be tested by some recognised standard in every case, and if found in a dangerous state, operation should be postponed until medication shall have brought it back to a normal condition. F.

Treatment of the Puerperium.—In an interesting paper on this subject Kroemer (*Deutsche Med. Wochenschrift*, 1907, Nr. 1-4) begins with the prophylactic measures which ought to be taken to prevent disturbance during the puerperium. When there is a pathological vaginal secretion during pregnancy, he recommends shaving and thorough disinfection of the vulva with at the same time vaginal douching twice daily with sublimate solution 1 in 2,000. In such cases also, internal examination must be avoided if possible. He does not agree with Zweifel's proposition that blood clots should be removed from the vagina post partum. When the lochial secretion is profuse and smells badly, the vulva must be particularly well disinfected, and the vagina douched with peroxide of hydrogen or potassium permanganate. He warns against internal disinfection when labour is progressing spontaneously. Before operative delivery the field of operation must be cleaned with lysol 1 per cent. solution, if the vaginal contents are decomposed and smelling. If the uterus is probably the seat of the cause of the fever, it must be douched out after the operation with alcohol. In order to prevent relaxation of the abdominal walls and its consequences, the author advises that the patient shall wear an abdominal belt from the sixth month of her pregnancy. The skin must be taken care of by baths, etc. Varicose veins must be treated with bandages, baths, and massage. He also recommends Prochownik's diet. The women should practise during pregnancy to use the bed pan in bed. If there has been any crushing of the bladder, for example after difficult forceps or pubiotomy, a catheter must be kept in the bladder during the first eight days, and the bladder douched daily. Immediately after labour the abdomen is to be bound from the trochanters to the costal margin. Towards the end of the puerperium any retroflexion or descent must be corrected with a pessary. He warmly recommends Bier's treatment for mastitis. He impresses the importance of combining, in cases of puerperal sepsis, the removal of any infection from the uterus with a careful inspection of the perineum, the vulva, the vagina, and the cervix. When retention of portion of the placenta is suspected the uterus should be examined digitally, and, if necessary, curetted with a large blunt curette. If in cases of thrombo-phlebitis operative measures are decided on, he advises laparotomy and ligature of all the four veins. He binds himself to nothing as regards total extirpation of the septic uterus. For the general treatment of puerperal fever he recommends nuclein, and at the same time subcutaneous infusion of normal saline solution to increase the leucocytosis, and quinine or ergot to excite the uterine contractions. He also recommends the serum treatment. G.

The Signification of Slow Pulse with Rise of Temperature during the Puerperium. — Merletti (*Ginecologia*, 1906, Nr. 4) states that in some cases in which the temperature rises very often to a considerable height while the pulse rate remains practically normal the prognosis may be regarded as favourable, and he then proceeds to arrange the causes which he has experienced of this condition. It is especially associated with intestinal disturbances, on the one side diarrhœa and on the other constipation with absorption of toxic substances, also with lochiometra for example in cases of pathological anteflexion of the uterus, and also in cases of pure nervous disturbances. The author gives several examples for each of these kinds of fever, and especially interesting is the history of a puerpera in whom the great anxiety to nurse her child and the daily fiasco of trying to accomplish this was associated with a high temperature up to 40 degrees. The most important and the most frequent is the intestinal fever; it begins not infrequently with a rigor and can reach a great height, while the pulse rate remains normal or rises very slightly. The author believes that when the pulse is slow in spite of a high temperature, and when there is no proof of disease in the generative tract, the presence of a serious puerperal condition need not be considered, and that such local treatment as uterine douching, etc., is useless and should not be employed. G.

The Cysts of the Corpus Luteum.—In an extract from an article on this subject, Grusdew (*Zentralbl. für Gynäk.*, 1907, Nr. 50) is reported as having stated that ovarian abscesses, malignant neoplasms, and cysts develop in the corpus luteum, and that the cysts are the most frequent. The cysts which have been described so far were usually about the size of an apple. The author operated on and examined a cyst of the corpus luteum as big as a man's head. The corrugated appearance of the inner surface of the tumour was badly developed, and the lutein layer was absent. This is to be explained according to the author by the great size of the cyst and the excessive thinning of its walls. In addition to this the author has observed two cases of hæmatoma of the corpus luteum. In both cases multiple cystic degeneration of the corpus luteum and excessive production of lutein cells were to be observed in the ovaries. There was no appearance of malignant deciduoma in the genital tract. These cases prove in the author's opinion that a hæmatoma of the corpus luteum may reach a large size, even as large as a child's head. The contained blood comes from the capillaries of the lutein cell layer. The epithelium which lines the interior of cysts of the corpus luteum is in some cases the morphologically altered endothelium of the capillaries of the lutein layer. G.

Necrosis and Suppuration in Myomata.—O. v. Franque (*Zeitsch. für Geb. und Gyn.*, Bd. LX., Hft. 2) reports three cases of necrosis in uterine myomata. In the first case of these, the necrotic tumour had perforated into the uterine cavity, and was partly expelled into the vagina, while in the second patient the uterine contraction produced by the necrotic tumour had caused a perforation of the external wall of the uterus into the abdominal cavity, and in the third into the layers of the broad ligament. The age of the patients varied between 31 and 49 years. They all recovered after operation. In another case suppuration occurred in a large interstitial uterine myoma. The patient, æt. 51, III.-para., had had the menopause. The most remarkable point was that the suppuration occurred one year after the menopause through the blood stream without any apparent cause. The following are among the author's conclusions:—The sub-febrile temperatures so frequently observed in cases of total necrosis of interstitial myomata are to be regarded as a result of absorption of pyogenic substances from the necrotic masses. In all cases of soft myomata, hooking up of the tumour must be avoided during operation, in order that the rupture of the capsule with its possible disastrous results may be avoided. G.

On December 9th there was announced the result of the poll of the 747 governors of Hampstead General Hospital regarding the proposed amalgamation of the North-West London Hospital with that institution, as suggested by the King's Hospital Fund. The in-patients' department of the North-West London Hospital has been closed, but the out-patients' department, it is proposed, should be continued as a branch of the Hampstead Hospital's work, the latter institution to have staff consultants, like other general hospitals. Much feeling has been aroused amongst Hampstead medical men on the latter proposal. The poll resulted in 195 governors being in favour of the amalgamation, and 187 against.

Medical News in Brief

Royal College of Surgeons, England.

At a meeting of the Council held on Thursday last, Mr. Henry Morris, President, in the chair, it was determined to advertise the vacant office of Conservator of the museum, and to invite candidates to send in their applications before February 1st next. A report was received from the Museum Committee recommending certain alterations in the standing rules relating to the office. A report was received from the Board of Examiners in Dental Surgery regarding a resolution adopted by the British Dental Association at its annual meeting with reference to the period of instruction in mechanical dentistry. Upon the recommendation of the Board of Examiners, the Council determined to adhere to their regulation prescribing not less than two years' instruction. The Board further reported that they had considered the application from the University of Leeds for the recognition of the dental department of that University, and the Board being satisfied that the requirements of the College had been complied with in regard to the appointment of the staff, the scope of the courses of instruction, and the opportunities for hospital practice, it was decided to add the University to the list of dental schools recognised for the education of candidates for the Licence in Dental Surgery of the College. Mr. Clinton T. Dent, Surgeon to St. George's Hospital, was re-elected a member of the Court of Examiners. The report on the annual meeting of Fellows and Members, and the resolutions carried thereat, was postponed to a future meeting of the Council.

The President reported the proceedings of the General Medical Council at their recent Session, and a vote of thanks was given to him for his services as the representative of the College. He further reported that he had been asked and had consented to serve on a Committee of that Council which has been appointed to ascertain what legal provisions exist in the Colonies and Dependencies of the Empire and in foreign countries for the prevention of medical practice by other than legally qualified persons, and to consider what steps should be taken to procure effective legislation for the same purpose in the United Kingdom of Great Britain and Ireland.

With reference to a letter from the Deans of the medical faculties of the Universities of Leeds, Liverpool, and Sheffield, suggesting the desirability of holding the primary examinations for the Fellowship at other times of the year than May and November, the Chairman of the Committee, to whom the letter had been referred, stated that the Committee proposed to postpone their report, with the object of ascertaining the views of the several medical schools upon the proposed change before submitting any recommendation to the Council upon the subject.

Murderous attack on a Medical Man.

Henrietta Fitzgerald, 30, described as a machinist, living in Burton Crescent, was charged on remand, before Mr. Mead, at Marlborough Street Police Court, on Saturday, with having maliciously wounded Dr. Ernest Cranmer Hughes by striking him on the head with a hammer.

The woman, who was well dressed, was accommodated with a seat in the dock. She, it appeared, fancied she had a grievance against the doctor, and, meeting him in Dean Street, Soho, on November 22nd, struck him on the head with a hammer, injuring him so severely that he had to be taken to Guy's Hospital. When she was arrested she exclaimed, "I wish I had killed him. I meant to have a revolver, but didn't have enough money."

Dr. Hughes now for the first time attended court, and gave evidence. He said he was assistant surgeon at the Lock Hospital, Dean Street, Soho. He first saw the prisoner the last Friday in August, when she was suffering from a certain disease. During September he received two letters from her, which he answered. He went away for his holidays, and when he returned in October he again saw her in Dean Street. She asked him for a certificate with reference to an operation she fancied had been performed on her, but which had not, and he refused to give her one. Subsequently he received a letter from the Registrar of the General Medical Council. He handed the letter to the secretary of the Lock Hospital. Afterwards he was asked to attend a meeting of the board of the hospital, and after the matter complained of had been investigated, nothing was done. From the letters he received from her he thought she might be insane. On November 22nd, just after he left the hospital, the prisoner came up to him and said, "You are Mr. Hughes, are you not?" He replied "Yes." Whereupon she struck him on the arm with a brown paper parcel, which contained the hammer produced. She became very excited, a crowd collected, and he was going to give her in charge. While looking round to get a policeman she struck him on the left side of the head, just above the ear, with the hammer.

Mr. Mead committed the prisoner for trial at the Central Criminal Court.

The Army and Navy Male Nurses' Association.

THE object of this co-operation is to afford to the public the opportunity of engaging thoroughly well-trained male nurses and sick attendants of assured good character. The *personnel* of the society is composed solely of retired non-commissioned officers and men of the nursing section of the Royal Army Medical Corps, and of members of the sick berth staff of the Royal Navy. No man's name is entered on the register as a nurse until he has obtained his certificate of three years' training in the military hospitals, or, in the case of the Navy, until he has completed his first term of service, and unless he can furnish the fullest evidence of good character. The selection of men for admission on the register is made by the executive committee after the fullest examination of each candidate's records and testimonials. The co-operation will be able to supply, in addition to male nurses, asylum attendants, masseurs, dispensers, valets or travelling attendants, laboratory and hospital porters, P.M. porters, operating theatre attendants, and assistants in X-ray and electrical departments of hospitals. It is estimated that the sum of £2,000 will put the society upon a sound basis, and enable it to commence work at once. All communications to be addressed to the Hon. Secretary, Miss Ethel McCaul, R.R.C., at the offices, 47B, Welbeck Street, Cavendish Square, London, W.

Changes at St. George's Hospital.

A SPECIAL meeting of the governors of St. George's Hospital was held on December 9th for the purpose of considering some important changes in the management of the institution. Hitherto the offices of secretary and superintendent have been combined, and for some time this arrangement has been found to be inconvenient. The whole matter has been thrashed out by the committee, and a scheme was submitted to the court of governors. It was decided to appoint a medical superintendent who should reside in the hospital, and a secretary who should be allowed to live at his private house. Under the old rules the office of secretary was open only to bachelors and members of the Church of England, but the governors have now taken a broader view, and the official may be a married man and is not required to undergo a religious test. The meeting was presided over by Mr. A. William West, the treasurer, and amongst the forty governors who attended were Lord Arthur Hill, Captain C. B. Balfour, Sir William Bennett, the Hon. Dudley Fortescue, the Hon. Sydney Carr Glyn, Dr. T. Ridge Jones, and the Rev. A. G. Locke.

The Irish University Question.

AT a full meeting of the staff of Trinity College, Dublin, summoned by the Provost on Saturday, the following was passed unanimously:—

"That, fully realising the importance of a settlement of the University question, this meeting of the staff of Trinity College and members of the Academic Council think it undesirable to express any opinion on proposals which have not yet been formulated as a Government Bill, but they think it right to re-affirm the declaration contained in the statement issued by the Executive Committee of the Dublin University Defence Committee in March, 1907—viz., should the Government determine to introduce a measure which, while leaving to Trinity College and the University of Dublin their present independent and unsectarian character, would at the same time be acceptable to our Roman Catholic fellow-countrymen, it would be a matter of supreme satisfaction to all who are interested in higher education in Ireland, and who desire a final settlement of the whole question. We, for our part, have confined ourselves to working out our solution. We have not thought it our duty either to advocate or oppose any scheme for the satisfaction of the reasonable claims of Roman Catholics which does not interfere with our own development along undenominational lines."

Royal Academy of Medicine in Ireland.

AT a meeting of the Obstetrical Section of the Royal Academy of Medicine, held on Friday last, the following resolution was unanimously adopted:—

"That the Obstetrical Section of the Royal Academy of Medicine regard the recommendations of the General Medical Council regarding obstetrics teaching as in many cases a very great advance on the present conditions. The section, however, considers that the suggested alterations of the period of attendances on a Maternity Hospital from six months to three months would not be advisable or practicable. The section considers that instead of reducing the attendances, the licensing bodies should adopt such regulations as will insure the regular attendances of the students at the clinical teaching of the hospitals. With regard to the adoption of a practical examination in midwifery and gynæcology, the sections consider that such a step is most desirable, and urge its members to aid it by all means in their power."

PASS LISTS.

Royal College of Surgeons of England.

AT an ordinary meeting of the Council of the College held on the 12th inst., the following members of the College, having passed the required examinations and conformed to the bye-laws, were admitted Fellows of the College:—

Hugh Ainsworth, captain, I.M.S., M.B., Ch.B.Vict.; William Appleyard, M.B., B.S.Lond.; E. W. Bain, M.B., B.S.; W. E. Brierley, M.B., Ch.B.Vict.; Hubert Chitty, M.B., B.S.; Colin Clarke, M.B., L.R.C.P.Lond.; A. J. Couzens, L.R.C.P.Lond.; Millais Culpin, M.B., B.S.; W. E. Fisher, L.R.C.P. Lond.; J. G. French, M.B., B.S.; H. T. Gray, M.A., B.C., Cantab.; Henry Hardwick-Smith, M.B.Cantab., L.R.C.P.Lond.; S. C. Hayman, L.R.C.P.Lond.; Reginald Jamison, M.A., M.B., B.Ch.Oxon.; Thomas McPherson, M.D.McGill; R. D. Maxwell, M.D.; Edwin Maynard, L.R.C.P., D.P.H.Lond.; W. S. V. Stock, M.B., B.S.; Philip Talbot, M.B., Ch.B.Vict.

The following candidates, not being members of the College, were also admitted Fellows:—L. R. Braithwaite, M.B., Ch.B.Vict.; K. McKenzie Duncan, M.B., Ch.B.Glasg.; Edward Gillespie, M.B., Ch.B.Glasg.; J. L. Falconer, M.B., Ch.B.Vict.; David Ligat, M.B., C.M.Glasg., D.P.H.Vict.; H. F. Shorney, M.D., B.S.Melb.

The following is a list of new licentiates in dental surgery:—Stanley Bellman, R. D. Bennett, L. W. Biscombe, John Button, J. W. Doherty, W. A. Dredge, William Drew, R. Dent, H. G. Dumayne, J. G. Fernie, E. E. Fletcher, A. W. Gant, Percy Gee, R. J. Gibbings, J. K. Hargreaves, Ernest Harrison, A. F. Hochapfel, Graham Hunt, C. E. James, T. N. Jeffries, H. E. Jones, A. T. Knight, Isaac Levy, Oswald McGowan, J. F. Maguire, L. T. B. Matthews, Federico Montuschi, F. R. H. Myers, C. R. M. Peaty, C. G. Plumley, P. J. Proud, Lewis Richter, E. G. Robertson, C. R. Rudolf, F. H. Salter, R. A. Scott, H. V. Sharp, Sydney Shovelton, A. W. Smith, I. S. Spain, W. M. Swan, A. C. Tippett, A. I. Ward, R. G. White, and R. T. Wood.

Diplomas of membership of the College were issued to John Lewis, Univ. Coll. Hosp., and to J. L. Todd, McGill Univ., Canada.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Saccharine.—There is some evidence that diabetes is a microbic disease in some cases, though at present the theory does not fit all the facts of the case. The idea that it is so obtains a certain amount of confirmation from the fact that it is endemic in certain parts of Bengal, and not in the surrounding districts and provinces.

Mr. R. Wright.—We have no knowledge of a sanatorium that accepts patients at the very moderate fee mentioned. There are, of course, charitable institutions in which patients are received without charge, on the recommendation of subscribers, but we take it this is not what you are seeking. There is a "Handy Reference List" published at 6d. by Pullman and Sons, Limited, Thayer Street, London, giving a complete list of sanatoria with their charges, which we would advise you to consult.

Edinburgh Student.—We know of no work on anatomy that answers your requirements so fully as Professor Buchanan's recent "Manual of Anatomy" (University Series of Text-Books), as it is systematic and practical, and includes embryology. The illustrations are in colours, and will be found very helpful.

PERSONAL PARAGRAPHING.

The *Evening Standard* of December 7th, contained the following paragraph:—"One of the King's Physicians Extraordinary, a Knight of Grace of St. John of Jerusalem, Sir Joseph Fayrer, reached the venerable age of eighty-three, and in the mild climate of Falmouth, where he is passing his declining years, he still devotes much of his time to literature and the fine arts. Apart from his lifelong practice as a surgeon, and his long service in India, including the Mutiny, the professorship of the Medical College of Calcutta, and the presidency of the Medical Board of the India Office, he has written many books, both professional and otherwise. Among the better known of the latter class are 'With the Prince in India,' 'The Life of Sir R. Martin, C.B.,' and 'Recollections of My Life.'"

May the memory of the good deeds of all of us survive as vividly!

D. S.—We are much obliged for your kind compliments. The incidents, regrettable enough in themselves, are being worked for all they are worth to throw odium on the profession, and we feel it our duty to expose such sorry tactics.

L. M.—There is no valid objection to the course you propose, and you are justified in taking it without reference to anyone, as you have been so badly treated. It would be better, however, to take a philosophical view of the matter, and call on your fellow practitioner to make a personal explanation of your motives in doing so. Then no blame could possibly be imputed to you.

N. R. G.—1. Yes. We agree entirely. 2. Yes, but with the reservation you mention. 3. No. It does not follow, and your ingenious theory does not hold water.

Promotion.—The Indian Medical Service offers excellent opportunities in the direction referred to. The next examination for 16 Commissions in the Service will be held in London on Tuesday the 28th. January, 1908, and the four following days. Particulars regarding pay. promotion, &c., in the Service, and the necessary forms of application. can be obtained from the Military Secretary, India Office, London. You will find fuller particulars on referring to our advertisment columns.

Meetings of the Societies, Lectures, &c.

Wednesday, December 18th.

Royal Microscopical Society (20, Hanover Square, W.).—8 p.m.: Mr. E. Large: Exhibition of Selenite Specimens showing interesting features due to Twinning. Papers:—Mr. J. Murray: Some African Rotifers.—Mr. E. M. Nelson: (1) Gregory and Wright's Microscope; (2) A Correction for a Spectroscope.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. J. Cantlie: Clinique (Surgical).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Thursday, December 19th.

Child-Study Society (Parkes Museum, Margaret Street, W.).—8 p.m.: Lecture: Miss A. Ravenhill: Some Results of an Investigation into Hours of Sleep amongst Elementary School Children in England.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m. Gynæcological Operations (Dr. Giles).—Cliniques:—Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 Throat Operations (Mr. Carson).

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Hutchinson: Some Diseases of the Newly Born.

Central Midwives' Board (Caxton House, Westminster) at 2.45 p.m.

Friday, December 20th.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Appointments.

Beattie, Thomas, M.D.Durh., M.R.C.P.Lond., Honorary Physician to the Royal Victoria Infirmary, Newcastle-upon-Tyne.

Bolam, Robert A., M.D., B.S.Durh., M.R.C.P.Lond., Honorary Physician to the Skin Department, Royal Victoria Infirmary, Newcastle-upon-Tyne.

Cassidy, M. A., M.B., B.C.Cantab., M.R.C.P.Lond M.R.C.S.Eng., Resident Assistant Physician at St. Thomas's Hospital, London.

Codd, J. Alfred, M.D., B.Sc.Lond., Physician to the Wolverhampton and Staffordshire General Hospital.

Gowring, B. W. N., M.R.C.S., Honorary Surgeon to the Dorset County Hospital.

Smith, J. B., M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Hertford District of the county of Hertford.

Timms, Alec Boswell, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Visiting Medical Officer to the Cardiff Workhouse.

Vise, J. N. B., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Act for the Axminster District of the county of Devon.

Vacancies.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary, £175 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to the Medical Superintendent.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Casualty Medical Officer. Salary, £200 per annum with lunch. Applications to the Secretary. (See Advert.)

Corporation of Manchester.—Assistant to the Medical Officer of Health. Salary, £200 per annum. Applications to the Chairman of the Sanitary Committee, Public Health Office, Town Hall, Manchester.

Suffolk District Asylum, Melton.—Second Assistant Medical Officer. Salary, £160 per annum, with board, furnished apartments, attendance, and laundry. Applications to the Medical Superintendent.

Bristol General Hospital.—Senior House Surgeon. Salary, £120 per annum, with board, residence, etc. Applications to the Secretary.

Liverpool Hospital for Consumption.—Resident Medical Officer for the Sanatorium at Kingswood, Delamere Forest. Salary, £400 per annum, with a house (unfurnished). Applications to Alfred Shawfield, 77a, Lord Street, Liverpool.

Cardiff Union.—Assistant Medical Officer. Salary, £130 per annum, with rations, apartments, attendance, and washing. Applications to Arthur J. Harris, Clerk, Union Offices, Queen's Chambers, Cardiff.

Births.

Riley.—On Dec. 12th, at 3, Culverden Gardens, Tunbridge Wells, the wife of Francis Riley, M.D., B.S., F.R.C.S., of a son.

Marriages.

Berry—Logan.—On Dec. 14th, at the Wesleyan Church, Hammersmith, Sidney M. Berry, M.A., younger son of the late Dr. Charles Berry, of Wolverhampton, to Helen, eldest daughter of J. M. Logan, of Bedford Park, Chiswick, W.

Deaths.

Cary.—On Dec. 10th, at 71, Thorney Hedge Road, Gunnersbury, Middlesex, Tristram Cary, M.D., third son of the Rev. Anthony Cary, Rector of Glendermott, Londonderry.

Falls.—On Dec. 11th, at Curraghmore, Bournemouth, Alicia, Mary, widow of William Stewart Falls, M.D.

Spong.—On Dec. 13th, at Lynsted, Beckenham, William Spong M.R.C.S., L.R.C.P., eldest son of the late William Nash Spong, of Faversham, Kent, aged 52.

Williams.—On Dec. 13th, at Holt Street House, Wrexham, Joseph Llewelyn Williams, M.B., aged 63.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXV. WEDNESDAY, DEC. 25, 1907. No. 26.

NOTES AND COMMENTS.

Roll of Merit.

THE distinctions awarded by the State for medical and scientific eminence are few and niggardly, and we should like to see them greatly enhanced. But, while waiting for that *desideratum*, we may content ourselves with a new Order of Merit, not the one recently conferred on Miss Florence Nightingale, but that created by the *Vaccination Inquirer* for districts and unions having between 40 and 50 per cent. of the children born in them returned as unvaccinated. This strange honour was instituted in 1903, and thirty-three names were inscribed on the roll; in 1904, the last year presumably for which complete returns have been issued, the number is thirty-six. Three London Unions, Mile End Old Town, Poplar, and Bethnal Green figure in it, together with two registration counties, Northampton and Bedford, and fifteen provincial unions. The highest "honour" belongs to Hinckley, which has a percentage of unvaccinated births amounting to 48.4; while the wooden spoon belongs to Leighton Buzzard, with 40.2. The *Vaccination Inquirer*, which seems to make very little inquiry about vaccination, and to express a great deal of dogmatism about it, naturally rejoices at the increasing list of the claimants to its distinctions, but bewails the loss of three old recipients which have fallen away from the faith, whether as the result of a small-pox outbreak or not we do not know. We do not gather if any token of the "honour" is bestowed upon the successful ones, or whether the barren distinction of enrolment is all the consolation achieved. If it did not savour of idolatry one should be induced to suggest that a golden calf might be awarded to the union having the highest "percentage not cowpoxed": such an emblem might stimulate noble emulation and serve as a totem for the anti-vaccination tribe. But perhaps a model of a lunatic asylum might be more appreciated.

"Rice" Treatment.

OUR contemporary, *John Bull*, for December 14th, contains the following notice:—"Senile (Bath).—We are not medical experts, and cannot take upon ourselves the responsibility of advising the 'Rice' or any other treatment for rupture." The first thought that occurs is, *O si sic omnia*. When the veriest rags of papers do not hesitate to give medical advice and to publish lying statements about doctors' errors, it is something of a relief that one paper at least should proclaim its disqualification to give expert advice on technical subjects. But we confess, if we may humbly assume the title of expert, that we are as ignorant of the "rice" treatment of rupture as our contemporary. Indeed, beyond connecting the word with a theory of beri-beri and a simile for cholera stools, "rice" suggests but little to us in medicine, and how it should be used in the treatment of hernia is a "poser." The rupture quack is always somewhat of a mystery; how he manages to persuade his victims to do anything except wear a truss and yet imagine benefit is difficult to conceive. Still more so is that the seniles of Bath should regard *John Bull* as an authority on the disease, except on the well-recognised principle that there are many people who think all editors are Admirable Crichtons and Dr. Murrays rolled into one.

Limericks and Insanity.

THE limerick craze has been a godsend to the papers which have opened their columns to that intellectual form of entertainment, for the numbers of would-be prize-winners who have bought their issues, not for their literary charm but for the limerick coupon, must have had a prodigious effect on their circulation. It is sad to record that a poor fellow, the tramp-master of the Cheltenham Workhouse, should have been literally so "crazed" by these competitions as to take his own life. At the inquest it was proved that he had hanged himself after unsuccessfully attempting to cut his throat with a razor, and medical evidence showed that he was much excited over limerick competitions, and was greatly disappointed that he had not gained a prize. The Coroner was shown between fifty or sixty counterfoils of sixpenny postal-orders, and it was said that he had spent a large amount of money in going in for competitions. Moreover, many "last lines" were produced in Court. The victim had sent a letter, from which it was evident he was much annoyed at his non-success, to each of the papers in which he had competed. An extract from this ran: "I have read the lines to which prizes have been awarded in your limerick contests for some weeks past, and if there is no favouritism or fraud in the contests, then it is time the adjudicators consulted a medical man and had their heads examined; most of the winning lines have no merit whatever." Although the jury returned a verdict of "suicide whilst temporarily insane," we are tempted to doubt the insanity of a man who had diagnosed the situation with such acumen, and given such excellent advice to those concerned.

Notification Errors.

IN the South-West London Police Court, Dr. S. A. Mugford, of Balham, was recently summoned by the Wandsworth Borough Council for failing to notify to Dr. Caldwell Smith, Medical Officer of Health for Wandsworth, a case of infectious disease. The defendant pointed out that he tried to do everything possible to acquaint the medical officer. He had telephoned to the Public Health Department of the Borough Council, and received a message to say that Dr. Caldwell Smith was absent, and that there was no one to receive the official notification. He thereupon communicated with the Metropolitan Asylums Board and had the patient removed. When asked why he did not send the notification by post, he said he wanted the patient removed immediately, and if he had posted the intimation, a day's delay in the removal would have taken place. The caretaker at the Borough Council offices, a curious official to use for the purpose, said that he had not received the intimation, but Dr. Mugford was quite positive about the message having been received. The magistrate said that it was more an act of inadvertence than anything else that Dr. Mugford had not actually sent the formal certificate, and if it was the case that notifications could not be received at the Town Hall at any period of the day, there must be a screw loose in the department somewhere, and the sooner it was remedied the better. He imposed a penalty of one shilling only, and sharply declined to allow the prosecution their costs. We presume that, a technical error having been committed, it was impossible not to convict, though that is by no means certain, but the smallness of the penalty and the refusal of costs sufficiently indicate the magistrate's opinion.

And their Results.

WE do not hesitate to characterise the use of the Police Court for the purpose of getting a penalty out of a medical practitioner who has notified a case in every way except by using a certain form as not only a blunder, but a distortion of the legal process. And when to that is added the fact that the administration of a health department of a large London borough is so conducted that urgent notifications cannot be received and acted upon during the daytime, it strikes us that justice demands that the position of defendant and prosecutor should be reversed. The notification of infectious diseases is not an end, but a means to an end, and if the power to use the legal means provided by the Act is tyranically and arbitrarily used, not only is public health administration brought into proper contempt, but it fails in its most important function, that of maintaining proper relations with the real health guardians of the people, namely, the medical practitioners. We lately had occasion to comment on the protest made by the Manchester Medical Guild against the action of the health department of that city in invading the privacy of patients' houses and bedrooms in defiance of their own and their doctors' wishes. We deplore the tendency that shows itself in various quarters for some health departments, now that they have come into being by medical advice and support, to assume towards both the people and the medical profession these bureaucratic methods which are as ill-advised as they are un-English. Unless health authorities work with the community in a sympathetic and considerate manner, their power will properly be curtailed, and the advance of practical hygiène delayed for years. The Notification of Births Act puts a new and most powerful weapon in their hands, and if it be employed in any but the gentlest and most beneficent fashion, it will utterly defeat its own end.

A Happy Hunting-Ground.

THERE is a happy land for doctors, but unfortunately it is situated at some distance. A correspondent of the *Glasgow Evening Times*, however, draws attention to it, and his description makes the mouth of the British medical struggler water. The land of delights is New Zealand, whose natural charms are sufficiently well known not to need description here. But over and above its charming climate, its beautiful scenery, and its virile population, New Zealand, says this gentleman, quoting another writer, could accommodate five hundred more doctors, and supply them with a *clear* income of £400 to £500 a year. In the large towns incomes running up to £2,000 a year are not out of the way, but the ordinary country practitioner is wanted, not in single spies, but in half a battalion, and the Dominion lies at his feet. Says one writer: "This may be a help to many who are wondering when they will find a practice. Let them make straight for New Zealand and get out into the country and have a good time, instead of a wearisome wait on 'dead men's shoes' in our home cities." The prospect is so alluring as to tempt us to fling down the pen and seek the shipping agent; but we must warn our readers who are longing to be off that vaccination is not popular in New Zealand, and that "doctors who depend on this operation are looked on somewhat suspiciously." Alas! all amber contains its fly.

LEADING ARTICLES.

MIDWIVES IN DEFAULT.

THE Central Midwives' Board has, thus early in its career, been called upon freely to exercise its penal powers. A number of licensed midwives have been struck off the register, and it is a matter of interest, as well as of importance, to the medical profession, to realise the conditions under which the particular offences in question were committed. There is, of course, something to be said on the score of the formation of a new register in which many worthless persons must necessarily be included, and from which it is obvious they will, in the nature of things, be rapidly excised. Some of the offenders show that they treat the fact of being licensed under the Act with absolute levity and contempt, inasmuch as they have not even satisfied the preliminary condition which demands equipment of each midwife with various drugs and appliances. Without such provision the most elementary skilled midwifery could not be conducted, for example, in the administration of antiseptic douches, the taking of temperatures, and catheterisation. That is a serious matter enough, chiefly because it shows the absolute indifference of a certain number of women to the responsibilities undertaken by them on registration. A similar recklessness led to several names being struck off for failing to call in a medical man in cases of retained placenta, ruptured perineum, and puerperal fever. This is precisely one of the things that it was predicted would take place were a hybrid class of registered women practising in one branch of medical work under the ægis of registration. This attitude was exemplified in an exaggerated degree in the case, to which we made allusion last week, of a midwife who prescribed quinine and iron to one of her clients. Indeed, one can readily imagine how hard it would be for a half-educated woman to grasp the fact that, although she might administer any one of the whole family of purgatives, solid or liquid, in any form or any combination, with the authorisation of the State that granted her a licence, nevertheless she might not prescribe any other drug in any other way. In this difficulty of drawing the line lies the great, and to many medical minds, the insuperable objection to the whole Act. The woman who is authorised to attend the simple confinement will find little difficulty in convincing herself that she is competent to deal with the difficult cases. It is hardly possible, on any other assumption, to explain the numerous cases in which licensed midwives have neglected to summon medical aid. The greatest and most appalling defect revealed in the whole of these charges, however, is the fact that women attending puerperal fever cases either failed to report the case, or neglected to use disinfectants and call in a medical man, or went on attending other cases, and thus spread this terrible infection. The fact of the matter is that it takes a long and careful medical training to recognise a morbid condition of the kind, and it is absolutely useless to expect the average ill-educated midwife to recognise the fact that her patient has been invaded by a deadly infection. Some of the women subjected to the disrupture of the Board had not even furnished themselves with the thermometer essential to the formation of an early diagnosis of the malady. On logical grounds, the man in the street will one day probably be forced to the conclusion, long since arrived at by the general practitioners of the United Kingdom, namely, that the conduct of labours should be left in the hands of qualified medical men and women, and that there is absolutely no need to set aside a special class of registered women for that particular work, any more than it is necessary to certify nurses to attend, say, pneumonia, broken bones, or skin diseases. Most medical men will probably agree that before receiving any recognition as a competent midwife a woman should have a prolonged and careful nursing education. Further developments under the Midwives Act deserve to be watched closely, as they may in no distant future demand great attention at the hands of the legislature when called upon to frame a fresh Medical Act.

THE FEEDING OF SCHOOL CHILDREN.

THE progress of Society towards the attainment of its ideals is seldom rapid, and perhaps it is well in some cases that advances should be made chiefly in response to well-ascertained shortcomings. Otherwise, so much is man a creature of impulse, the community might find itself kept in a more or less continual commotion by the pursuit of impossible ideals. In the case of public education there is still a great deal to be learnt in our treatment of school-children, apart from the altogether vexed questions of what we ought to teach them and the best way of imparting knowledge. For all that, the State has within the past few years made some noteworthy advances as regards the children who are educated at the expense of the public. Roused by the cry of national degeneracy, a great deal of attention has been recently paid to the physical conditions and requirements of the people. One of the indirect benefits of that awakened interest has been to focus a large amount of enquiry upon the schools. A general demand for the proper sanitary control of the educational environment has been followed by various salutary measures, and has culminated in the Act which for the first time institutes the systematic medical examination of scholars. The absolute necessity of such a provision is well illustrated by the increase for many years past of diphtheria, which is essentially a school disease. Then, again, who can doubt that the scarlatina problem, which is the despair of sanatarians, is largely influenced by the conditions of school-life? There is little need to labour the point, however, for it stands to reason that the bringing together of children in large numbers at an age when they are peculiarly open to attack by infectious disease is to multiply the already complex problem presented to the medical officer of health in the attempt to control the great zymotic maladies. Almost at the end of the series of new faiths came the sudden recognition of the fact that it is useless to teach starving children, and that the backbone of the nation might be strengthened to an incalculable degree by providing food for the State children whose parents were unable to fulfil that necessary duty. The outcome of this new gospel was the Provision of Meals Act, whereby local authorities were empowered to feed school-children at the public charge. This statutory permission was speedily taken advantage of in various large centres of population, among which may be mentioned Brighton, Birmingham, Bristol, and Manchester. Curiously enough, the greatest city, not only in the kingdom but also in the world, declined to use their powers under the Act. The consequences of this short-sighted policy are not far to seek. Every ill-fed child of the poorer classes of the community must inevitably become, sooner or later, a charge upon the State. So that Londoners, who to-day are saved a small direct tax to feed these foodless scholars, will in the long-run have to pay many times that amount to hospitals, workhouses, prisons, and Poor-law infirmaries. We are not concerned with the politics of the London or any other County Council. At the same time, as a medical journal, we cannot help feeling the deepest interest and anxiety when any well-conceived plan for advancing the collective stability of the public health is permitted to go astray by the apathy or short-sightedness of local administrations. It needs little argument to show that the refusal to make good so grave a defect in our social system as the existence of many thousands of children in a state of chronic semi-starvation must be to undermine the future of our race. No class of the community is in a better position than the medical profession to judge of the ravages worked by shortage of food amongst the poor, for they are brought into close contact with the facts themselves in all their phases. On the score of public health, and of the radical necessity of fostering the vitality of the rising generation, not to mention considerations of political economy and of ordinary humanity, we trust that wiser and better views will utimately prevail on this point in the London County Council, and that other local authorities in all parts of the kingdom will follow them in adopting this salutary Act. It is a weak alternative to draw upon the resources of private charity to replace what should, in our opinion, clearly be the recognition by public citizenship of an elementary duty. The springs of private benevolence are already seriously drained in attempting to satisfy the needs of the medical charities, which will suffer proportionately if donations be diverted to the feeding of the school-children by channels that must at their best be somewhat intermittent and altogether uncertain.

CURRENT TOPICS.

A Workhouse Scandal.

AN inquiry into the death, on December 4th, of a recent inmate of Wandsworth Infirmary, is being made by the Westminster Coroner under unusual circumstances. As the inquiry, which involves an explanation, is still incomplete, we refrain from comment upon the case. There is one point, however, to which the attention of all Poor Law medical officers should be directed, namely, the discharge of responsible nursing, dispensing, and other more or less directly medical services in the midst of a mass of other duties. One witness, who is alleged to have made some lapse, produced the following list of duties :—

(1) Assist with coaling and removal of ashes and poultice tins. (2) To obey all orders of the medical officers and stewards. (3) To bathe all male patients on admission, unless countermanded by the medical officer. (4) To search the clothes of the male patients when admitted, and place them in a numbered bag and rack in the clothing-store; make list of all articles, and put clothes away thoroughly dry. (5) Immediately hand to the steward all money, documents, or other valuables found on patients. (6) Bake carefully and thoroughly all foul clothes, underclothing to be taken to the laundry, and the whole afterwards placed in the clothing-stores. (7) To be responsible for the good order of the patients' clothing-store. (8) To assist in carrying patients or articles of furniture to and from the wards. (9) To take to the master all the clothes of deceased male patients, entering a list of the articles in a book. (10) To bake all foul bedding, clothes, etc., from the wards with great care, and disinfect any room when desired. (11) To assist every day with the patients' dinner, and convey milk to such parts of the infirmary as directed. (12) To collect the bottles for the dispensary, and deliver them to the nurses when the medicines are made up. (13) To wash the bottles for the dispenser. (14) To keep in good order the bottle-room, dispensary, store, drug-room, and the two bath-rooms of the male receiving ward. (15) To sweep daily and wash down on Saturdays, or more often if required, the disinfecting chamber, the yard adjoining the mortuary, and the steps leading to the subway. Also to take weekly turn in rotation with the other porters in the washing of the new bath-room, lavatory, etc. (16) To attend to the hall when required.

For this multifarious service the Guardians paid the munificent sum of £1 per week.

Inaccurate Prescriptions.

THE vital importance of the purity of accuracy of the ingredients of the physic compounded by chemists is self-obvious. In places where the matter has been put to the test startling results have been in various cases forthcoming. Only last week a London chemist was fined £5, or in default one month's imprisonment. The defendant did not appear, but he runs a good chance of the more serious punishment should he offend again in a similar way. At last the modern tendency of magistrates appears to incline towards greater severity. It would be hard to imagine a meaner or more injurious offence than that of substituting one preparation for another ordered by a medical man, no matter whether the motive be parsimony, convenience, or a desire to save time. As the gentleman who appeared for the City solicitor remarked, the matter was most serious because medical men depended upon accuracy in the making up of prescriptions, and Dr. Teed, the public analyst, had told them in his report that many drugs had been considered worthless, whereas in reality they had never been tried. Since April last 23 City prescriptions have been analysed, and no fewer than twelve of them were found to have been inaccurately dispensed. The state of trade morality thus disclosed reflects most undesirably on the main body of a class of men whom the public have learnt to regard with entire confidence.

An Alternative Drink for Alcohol.

A CORRESPONDENCE has been recently evoked in the columns of a London newspaper by a writer who advocated an alternative drink containing tincture of capsicum to allay the craving for alcohol. This caught the eye of a scientific gentleman, who promptly pointed out that tinctures, being made with spirit, to prescribe them in such cases was simply adding fuel to fire. This statement brought a number of medical men into the fray. One side maintained that tinctures could be made without alcohol. Strictly speaking, we fail to see how a non-alcoholic extract could consistently be called a "tincture," although most medical men are aware that it is possible to substitute for nearly all pharmacopœial tinctures a cheaper non-alcoholic preparation which is usually fairly equivalent from a therapeutic point of view. In the case of capsicum the extract, as a matter of fact, is much stronger than the tincture. The other class of medical critics emphasise the absurdity of objecting to the presence of such a fractionally minute dose of alcohol as that contained in a few drops of tincture of capsicum. Were the objection to alcohol pushed to the absurd degree of excluding all alcoholic preparations of drugs, the practice of physic would be handicapped thereby in a quite unnecessary manner. Incidentally, the interest shown in the discussion under notice illustrates the deeply-rooted belief of the vulgar in the possibility of specific drug cures, and, so to speak, antidotes for alcoholism. It would be difficult to produce an illustration of a more widely diffused popular error than the one upon which the fortunes of the drink "cure" is founded.

Incriminated Kippers.

A RECENT case in the High Courts opens up a novel and somewhat interesting point in the annals of ptomaine poisoning. It concerned an action for breach of warranty on the sale of an article of human food, namely, kippers. The defendants, in reply, denied the warranty, and alleged that all kippers supplied by them were sound and wholesome. The plaintiff one afternoon went to the defendant's restaurant and there partook of tea, bread and butter, and kippers. He noticed, he said in evidence, that part of the fish had a musty smell and did not eat any more. On the following morning he was seized with a violent attack of ptomaine poisoning, from which he ultimately recovered. His medical attendant stated that he had seen a similar case in his own household from eating an unsound kipper. Such cases, however, must be, we imagine, extremely rare. There is the cogent fact adduced on behalf of the defence by Dr. Alfred Stokes, Public Analyst for Paddington, who testified that poisoning from kipper was unlikely, namely, that the internal organs of the herring were removed in the course of preparation, which further involved salting, smoking, and drying—to say nothing of the purification by cooking. The jury had little difficulty in finding a verdict in favour of defendants.

A Public Medical Service.

The medical men of Birmingham have inaugurated an important scheme for the service of persons who are unable to pay ordinary fees. Any practitioner of twelve months' standing is qualified to join, provided he does not attend any sick clubs. Branch institutions are to be formed as necessary, and the medical officers are to be chosen from members. Each applicant has to be passed by one of the staff, who is responsible for fitness. A fee of at least twopence per week is to be paid by each person joining the organisation as a patient, and members are to be remunerated by a division of profits at stated intervals. Each patient is entitled to choose his or her medical attendant. The medical benefits do not cover confinements, consultations, disease arising from misconduct, serious injuries, dentistry, surgical operations, anæsthetics, and the supply of bottles or appliances. At the same time, it is proposed to make certain definite charges for night visits and extra services of various kinds. This appears to be a well-thought-out plan for facing the competition of hospitals, clubs, and other agencies that divert the poor from their proper medical attendants, namely, the general practitioner. The future of this energetic organisation deserves to be carefully watched by the medical profession generally. It is not the first time that the medical men of Birmingham have shown themselves capable of firm action in the attempt to defend their own interests.

The Manchester Epileptic Colony.

Manchester can boast of the finest epileptic colony in the world, and is making great efforts to seriously combat the disease. The medical report of the colony shows that during the past year, with the average number of colonists standing at 171, the total number of fits recorded was 29,444. These were unequally divided among the colonists; some had none, others had very many. One woman is reported to have had 2,814 in twenty consecutive days, with a maximum for twenty-four hours of 239. Another woman is said to have had 609 heavy major attacks in eight consecutive days. Both these patients are now going about; one of them has been free from fits since May. Another girl had 1,743 in February, 725 in June, and 565 in August. Such cases must obviously make great demands on the part of the staff. The epileptic colony movement is one that deserves the hearty support of philanthropic persons.

The "Brown Dog" Disturbances.

In our last issue we referred to some of the newspaper comments on the recent "brown dog" disturbances, remarking on the curious antipathy to the medical profession which they revealed. We are glad to see that some of the more respectable weeklies have shown more fairness, and have drawn attention to a point in connection with the disturbances which had escaped general notice. This is the refusal of the police authorities to allow the medical students the privilege accorded to all other sections of the public, of holding meetings in Trafalgar Square, and of walking in procession through the streets. So far as we can learn, there was no special disorder attached at first to the meetings of students, and we fail altogether to understand why they should have been specially selected for bludgeoning by the police. The disorder, indeed, seems to have been enormously increased, if not created, by the injudicious interference of the police authorities. The object for which the students met may have been a foolish one or a wise one, but it was no worse than the hundred-and-one other objects to which meetings in Trafalgar Square—undisturbed by the police—are devoted. It is hardly the function of the authorities to act as censors of the purposes of meetings in public places, and, as we suggested last week, Russian methods are out of place in London.

Copper in Spinach.

Two fines of £5 and £4, with costs, have recently been imposed in London police courts for selling preserved spinach in tins. Analysis showed in one case 4.70 grains of copper sulphate, and in the other 3.29 grains per pound. Medical evidence showed that the proportion of the copper salt mentioned would be injurious to health. Half a pound of such spinach would in some cases cause symptoms of irritant poisoning. The defendant stated that tinned spinach was used in every restaurant in London, and he claimed that the prosecution should be turned to the wholesale manufacturer from whom the tins came. Some years since a similar exposure took place in the case of preserved peas.

PERSONAL.

Dr. Deane Sweeting has been reappointed an Examiner in State Medicine at Cambridge University.

Dr. C. Guerin and Professor A. Calmette have been awarded the Louis Boggio prize for their researches on tuberculosis.

The King of Spain has conferred upon Dr. A. J. Rice Oxley, Physician-in-Ordinary to Princess Henry of Battenberg, the Order of Isabella the Catholic.

Under the will of Mrs. Fanny Peach, the Nottingham General Hospital has benefited to the amount of £1,000, and the Brompton Cancer Hospital to that of £500.

Among new members of the Council of the Metropolitan Hospital Sunday Fund are Sir James Reid, K.C.B., Sir Thomas Smith, K.C.V.O., and Mr. Thomas Wakley.

In our last issue we stated that Dr. Arthur J. Hall had been appointed Lecturer on Practical Medicine, University of Sheffield. In so doing we referred to Dr. Hall as Physician to the Sheffield Royal Infirmary. This should have been the Sheffield Royal Hospital.

The Liverpool medical students' annual dinner, which took place on December 14th, with Professor Rushton Parker as chairman, and Dr. John Owen as Vice-Chairman, was made the opportunity for presenting Professor Parker with his portrait in oils.

Among the new members of the General Council of King Edward's Hospital Fund for London are Lord Rosebery, the Speaker of the House of Commons, the President of the Local Government Board, Professor Osler, and Dr. Edwin Freshfield.

By the will of the late Mr. Thomas Berry, the Clinical Hospital for Women and Children, Manchester; the Altrincham Provident Dispensary and Hospital, the Salford Royal Hospital, and the Ancoats Hospital and Dispensary receive £1,000 each.

The honorary surgical staff and committee of the Margate Cottage Hospital have presented Mr. William Knight Treves, F.R.C.S., with an illuminated address, in appreciation of his thirty years' service.

A CLINICAL LECTURE
ON
THE SERUM TREATMENT OF TYPHOID FEVER
(ANTITYPHOID OPSONISATION).

By DR. CHANTEMESSE,

Professeur Agrege of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

DURING the last six years (April, 1901, to July, 1907) 5,621 cases of typhoid were admitted to the Paris hospitals with a mortality equivalent to 17 per cent. Since then a thousand typhoid patients have been treated in my fever wards with a mortality of only 4.3 per cent. My treatment comprises cold baths (24° to 30° C.), *plus* the injection of antityphoid serum.

In 1906, Professor Brunon, of Rouen, and Dr. Josais, of Paris, brought to the notice of the Academy of Medicine an improvement in the typhoid mortality under the serum treatment, this having fallen from between 10 and 12 per cent. to from 3 to 4 per cent. During the same period the mortality at the Val-de-Grace Hospital remained at 10.6 per cent.

Under the influence of the antityphoid serum the course of the disease is invariably modified in much the same manner. The evolution of the disease is sharply divided into two periods, the first being the stage of reaction following the injection, the second the process of defervescence. The first stage lasts from a few hours to several days, during which the temperature falls but slightly or not at all—indeed, it may even be a shade higher; then suddenly it goes down, the baths are required less frequently, and a steady decline sets in. The constitutional symptoms accord with the state of the temperature, and the patient does not feel any benefit until the onset of the second stage. When this sets in the patient may have hyper-pyrexia, necessitating several baths daily, but he feels better, the appetite returns, and he secretes plenty of urine. At this juncture there supervenes a very curious—indeed, characteristic—sign in typhoid fever, modified by the serum treatment—viz., a striking change in the vaso-motor system.

Every physician is familiar with the typical facies of the typhoid patient, in whom, in spite of the high central temperature, the tip of the nose, the hands and the feet are cold, and the nails are cyanotic. In patients treated with the serum, at the expiration of the stage of reaction the facies markedly improved. Colour returns to the cheeks, the stupor is modified, the hands lose their pallor and are warm, and the nails have a rosy hue. This improvement in the peripheral circulation persists throughout, and accounts for the wonderful improvement in the appearance of patients thus treated.

The improvement is the more marked the earlier the serum has been injected after the onset of the disease—that is to say, at a period before the organic resistance has been broken down, and can therefore react energetically to the treatment. I have not lost a single patient during the last six years in my fever service in whom the injection has been made within the first seven days of the disease.

When the serum treatment is resorted to late—and by late is meant more the gravity of the damage already done than the mere number of days—the results are less rapidly favourable. The serum cannot bring about the disappearance of the nervous lesions, nor prevent the necrotic intestinal lesions when already present.

The blood pressure goes up within a few hours of the injection, and may reach between 12 and 15 cm. of mercury; this is sufficiently well marked to enable us to dispense with cardiac tonics. The pulse rate usually declines with the temperature. It may rise somewhat in presence of an unusually intense reaction, but this is of no particular gravity. I have seen plenty of patients with a pulse rate of 150, which is regarded as of fatal significance, yet they recovered.

The urinary secretion greatly increases in amount. Whereas the polyuria usually only supervenes with convalescence, in injected patients it is observed in the course of a few days, and sometimes amounts to 8 or 10 pints. If there be albuminuria before the injection, it soon subsides after it, and it is very rare for patients who were not albuminuric when injected to become so afterwards.

The influence of the serum on the temperature curve is appreciable for ten or twelve days, after which either convalescence sets in or the temperature continues to fall until recovery, the attack being comparatively short, or else, in the graver cases, the defervescence is stationary for some days, remaining above normal, as if the remedy no longer produced any effect, then convalescence sets in in the absence of a relapse. In any case the relapse usually only lasts a few days, especially when the original attack has been severe.

Convalescence is usually rapid, especially in patients treated early. Nevertheless, those in whom the disease has been promptly arrested by the serum, must take great care for some weeks to come, for I have occasionally seen a patient relapse two or three months later. This persistence of the microbe is, indeed, a well-recognised occurrence, and is manifested by osteitis and periosteitis. In this connection I must mention the remarkable effects of a small injection of serum *in loco dolenti*. We are aware that, as a rule, osteitis is of protracted duration, and usually ends in suppuration requiring surgical intervention. As soon as there is swelling and nocturnal pain, we need only inject one drop of the serum into the centre of the lesion, whereupon, within a few hours, the pain subsides, the swelling disappears, and recovery takes place in two or three days. The same treatment is applicable in the event of orchitis or typhoidal mammitis.

The low mortality in my thousand patients is evidence *per se* that complications must have been infrequent. Intestinal hæmorrhage only accounts for 4 out of the 47 deaths, while perforation accounts for 19, so that the treatment appears to protect less against this complication than others. This is explained by the fact that the intestinal lesions are the first to occur, and are already present when the injection is carried out, hence the importance of injecting early. I have never met with intestinal perforation in patients injected within seven days of the onset.

I have made a number of observations in order to ascertain whether the conjunctivæ of typhoid patients displayed a marked sensitiveness to the bacillus which might be useful in arriving at a diagnosis. Such is actually the case, and it may be well for me to describe the mode of employment of the test. The test solution is prepared as follows: A layer of gelose in a flat bottle is inoculated with the virulent bacillus and placed in the warm chamber for 18 or 20 hours, by which time the surface has become covered with a culture, which is removed after adding 4 or 5 cc. of sterilised water, and the bacillary mass is poured into a large tube. This is heated over a water bath at 60° C. to destroy the vitality of the bacilli; it is centrifugated, and the bacilli are dried *in vacuo*. The microbial mass is rubbed down in an agate mortar, with a little chloride of sodium. When thoroughly rubbed down we add 4 cc. of sterilised water, and continue the process, gradually adding water to the extent of 100 grammes for, say, 3 grammes of the microbial mass. The tube is then set aside to repose for two days, heating it to 60° daily for half an hour. The supernatant liquid is then decanted. It is almost transparent, and, should any flakes be present, it is again centrifugated. It should be but slightly opalescent when it is slowly poured into ten times its bulk of alcohol. The alcohol becomes cloudy, and is allowed to deposit for three hours, when it is decanted, and the coagulum that has formed at the bottom is rapidly dried *in vacuo*. We thus obtain a yellow mass, which is rubbed down to a fine powder in an agate mortar. When to be used, the powder, which contains a small proportion of toxin adherent to a substance that reacts to the test for albuminoids, is triturated, and it dissolves slowly, in the proportion of 10 milligrammes to 1 cc. of water—that is to say, enough for twenty observations. Thus prepared, the powder keeps very well in a closed bottle. The resulting fluid should be opalescent and free from flakes.

One drop of the solution is dropped into the lower conjunctival cul-de-sac, the patient's head being thrown back to prevent it escaping. Within two or three hours there is a sensation of heat, and the redness extends to a caruncula; there is some weeping and fibrinous exudation. The effect attains its maximum in from six to ten hours after instillation. The intensity of the reaction depends on two factors: first, on the sensitiveness of the patient, which varies within wide limits; and, secondly, on the quantity instilled. The quantity given has been shown by experience to be sufficient to determine a reaction in typhoid patients, and not in others. But the typhoid toxin is irritating *per se*, and what we must rely upon is not the existence of a reaction, but its intensity and its persistence.

The point to which I attach particular importance, since I have never found it wanting in true typhoid, is the persistence of the redness. This persistence is easily detected by comparison with the untreated eye. It may persist for one, two, or even five or six days, after which it clears up. After upwards of 200 observations, I have never seen the slightest untoward effect. Fifty persons suffering from non-typhoidal diseases gave no reaction, with one exception—that of a tuberculous woman who had had typhoid two years before, and in this case it had disappeared on the following day. Sixty-seven patients with well-marked typhoid gave a positive reaction.

The most interesting feature of this research is the following: Several times at the onset, or in the course, of an attack of typhoid fever, the ophthalmo-diagnosis gave a positive result, while the sero-diagnosis was negative, and only became positive several days later. As a matter of precaution the ophthalmo-diagnosis should only be tried in eyes which appear normal and healthy, or naked eye examination and the reaction should be quite apparent after 24 hours. It is possible that this delicate reaction may ultimately lead us to include among typhoid affections slight febrile attacks in which the sero-reaction proves negative.

The serum I employ is obtained from horses in which intravenous injections of virulent microbes have been practised for a long period, or the soluble typhoid toxin injected beneath the skin.

The soluble toxin is prepared by cultivating in flat bottles, in a bouillon of ox spleen, very virulent typhoid bacilli. The bacillus develops on the surface, and the toxins are elaborated beneath. In seven days this is collected in small bottles, and heated to 55° C., and centrifugated. The injections in the horse must not be repeated at too short intervals, for each one determines a sharp rise of temperature, and the horse becomes immunised but slowly. Those give the best results that have been injected periodically for several years. The properties of the serum vary somewhat according to the lapse of time that has taken place since the last injection of toxin. It attains its maximum preventive power in about 20 days.

Only small doses are required, and I have been able, by using the serum of animals injected for several years, to use only a few drops for each injection, a dose sufficient to determine the modifications in the course of the disease already referred to.

The influence of an injection lasts about 10 days. I rarely make a second unless the disease displays a tendency to become protracted, and in such case the second injection should be less in amount than the first, for it sometimes gives rise to local tumefaction, a result that never follows the first injection.

Injected into healthy rabbits and guinea-pigs, the serum gives rise to no constitutional symptoms. Animals previously injected resist inoculation with a quantity of typhoid toxin that proves fatal to animals not so protected. If the toxin and the serum be injected separately but simultaneously, the action of the former is almost as intense as when no serum is used, but the leucocytic defence is vastly more rapid and energetic than in animals where no serum is used; moreover, the blood returns to normal much more promptly. If the injection of serum be made too late—*i.e.*, in presence of urgent symptoms of intoxication—the favourable reaction is, so to speak, inhibited, and is not produced. The effects of the serum last for some time, and animals that have been injected therewith six or seven days previously still manifest marked resistance to subsequent injections of the toxin.

In order to properly grasp the action of the immunising injection, we must examine the spleen and bone marrow of the animals under observation. The difference in animals thus treated and the control animals is so marked as to be visible even to the naked eye.

The effect in the healthy man and the typhoid patient is exactly the same as in animals. Phagocytosis is stimulated in a marked degree—in fact, the state induced in the organism of the typhoid patient by the injection of the anti-typhoid serum is one of opsonisation. This is shown by estimating the opsonic index in patients subjected to serotherapy. The opsonic index by Wright's method is the relationship between the power (to take up typhoid bacilli), which leucocytes possess in normal human serum, and the power which these same cells acquire under the stimulus of typhoid blood either before or after the injection of serum.

The opsonic index is somewhat variable, according as we are dealing with a slight or severe form of the disease. In mild cases the opsonic curve shows that the opsonic index is high even before the injection of serum—*i.e.*, 2.1 (unity being the normal). The day following the injection the opsonic index rises, reaching its highest point on the fourth day; then it falls a little as the injected serum is eliminated and defervescence sets in, while the patient's serum contains a progressively higher quantity of opsonines. When convalescence is well marked the opsonic index remains high for a month or so after recovery. When convalescence is protracted, the opsonic index is lower.

In severe cases the opsonic index is low before the injection, after which there is a sudden and marked rise during the three or four following days. This period, no doubt, corresponds to wholesale destruction of bacilli throwing toxic products into the blood of the patient already intoxicated by the typhoid fever, and the patient reacts by a rise of temperature which is the phenomenon of the reaction; hence the desirability, in severe cases, of restricting the destruction of bacilli by only employing very small doses of the serum.

Between the fourth and twelfth day after the injection the curve of the index falls, although remaining above what it was before the injection. Then in severe cases the index oscillates round a fixed point until recovery ensues.

We must avoid giving the patient too severe a shock or we run the risk of inhibiting the production of opsonines. When the case takes a turn for the worse, as, for instance, in the event of intestinal perforation, the opsonic index steadily falls until the fatal result supervenes.

Already in 1902 I pointed out that "the graver the illness the smaller must be the dose of serum." This struck many as a strange utterance, but it is now explained and justified by observation of the oposonic curves.

It may be asked why, being in possession of such a powerful means, I still employ cold baths. My answer is that the baths are necessary to assist the patient in resisting the pyrexial reaction that follows the injections. Anti-typhoid serum is not an absolutely complete treatment, but it is one of great power which we have to learn how to use. At Cairo, in 1902, I suggested that "by the addition of anti-typhoid serum to hydrotherapy the typhoid mortality might be reduced to 4 or 5 per cent." Five years have passed since that time, and a much larger number of cases of typhoid fever have been treated at the hospital, and I have nothing to modify in that suggestion.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Harry Campbell, M.D., F.R.C.P., Lond., Physician to the West End Hospital for Nervous Diseases. Subject: "The Diet of the Aged."*

ORIGINAL PAPERS.

INTERSTITIAL KERATITIS FROM A MODERN STANDPOINT. (a)

BY SYDNEY STEPHENSON, M.B., C.M.,

Editor of "The Ophthalmoscope."

IT would be difficult or impossible to over-estimate the diagnostic importance which attaches to some of the ocular stigmata of inherited syphilis. By their discovery the nature of many and many an obscure case has been cleared up. I can recall a couple of cases of necrosis recognised as syphilitic in one instance by the finding of disseminated choroido-retinitis, and in the other by the advent of interstitial keratitis. The most striking case with which I am acquainted, however, was related by Edmond Fournier in his monograph on late heredito-syphilis (" Recherche et Diagnostic de l'hérédo-syphilis tardive," 1907, p. 325). A man, æt. 34, was believed to be suffering from sarcoma of the pelvis, declared by three competent hospital surgeons to be beyond the reach of operation. The patient's elder brother, æt. 36, was examined by my friend Dr. Antonelli, with the ophthalmoscope, and found to be affected with positive stigmata of congenital syphilis. The result of this discovery was happy in the extreme. For after two months' treatment by mercurial injections and potassium iodide, the pelvic growth disappeared without leaving a trace and the patient was restored to perfect health. His remark was amply justified when he exclaimed: "*J'ai été sauvé par les yeux de mon frère.*"

Of all the ocular manifestations of inherited syphilis, none is better known or easier to recognise than diffuse interstitial or parenchymatous keratitis.

The disease is not exactly a common one. For example, Greeff, (*Die Keratitis interstitialis in ihren Beziehungen zu Allgemeinerkrankungen*, 1897) collected figures respecting 36,385 eye patients, and found that interstitial keratitis had been diagnosed in 297—*i.e.*, in 0.77 per cent. of the total number. Again, among 5,142 eye patients seen by me at the North-Eastern Hospital for Children, London, 49, or 0.95 per cent. were affected. The proportion would naturally be somewhat higher at a children's hospital than elsewhere.

The disease has been familiar to surgeons for many years. Wiilliam Mackenzie (" A Practical Treatise on the Diseases of the Eye," 1830, p. 419.") who takes in ophthalmic science the position occupied by Sir Thomas Watson in general medicine, was acquainted with the malady, which was called by him "scrofulous corneitis." Mackenzie noted its coincidence with deafness, a peculiar hoarseness of voice, swollen lymphatic glands, nodes on the tibiæ, and effusion into the bursa beneath the tendon of the extensores cruris, symptoms some of which we now recognise to be manifestations of inherited syphilis.

It was, however, reserved for Jonathan Hutchinson (" A Clinical Memoir on Certain Diseases of the Eye and Ear, consequent on Inherited Syphilis," 1863) to show that interstitial keratitis was " almost always a direct result of inherited syphilis," and to give a description of its clinical characters and morbid associations that is as truthful to-day as when he wrote it forty-four years ago. In particular, Hutchinson drew attention for the first time to the diagnostic value of certain malformations of the teeth often met with in cases of interstital keratitis.

A few years later James Dixon (" A Guide to the Practical Study of Diseases of the Eye," third edition, 1866, p. 95) went farther, and proposed to substitute for Hutchinson's name, " chronic interstitial keratitis," that of " syphilitic keratitis," since there existed, he said, " no special form of keratitis connected with acquired syphilis."

Still more recently, Hutchinson (" Syphilis," London, 1889, p. 75) has claimed that " interstitial keratitis in its typical form is always a consequence of syphilis, and is in itself sufficient for the diagnosis."

To some extent, however, the pendulum of professional opinion has now swung back to the views expressed so many years ago by William Mackenzie. The view current to-day, especially upon the Continent, is, that while parenchymatous keratitis is usually a manifestation of inherited syphilis, yet a proportion of the cases are due to other factors, among the more important of which are tuberculosis, acquired syphilis, influenza, malaria, and trypanosomiasis. In a word, it will scarcely be denied that interstitial keratitis is the local manifestation of some general disorder, be it syphilis or otherwise.

It will clear the ground if a few figures be quoted as to the relative frequency of inherited syphilis as a cause of interstitial keratitis. Davidson found 20 per cent., Alexander 35.3 per cent., Fournier 41.5 per cent., Hirschberg 61 per cent., Sæmisch 62 per cent., Horner 64 per cent., Mauthner 80 per cent., Bosse, 81 per cent., and Silex 83 per cent. of the cases to be due to a specific cause in the shape of inherited syphilis. Pfister (*Klin. Monatsbl. f. Augenheilkunde*, XXVIII., 1890 p. 114) found certain evidence of hereditary lues in 40.8 per cent. of his 130 cases and presumptive evidence in 23.8 per cent.—total, 64.6 per cent. Nettleship (" Diseases of the Eye," fifth edition, 1890, p. 120) found personal (54 per cent.) or family (14 per cent.) evidence of inherited syphilis in 68 per cent. of an unspecified number of cases, and in most of the remaining 32 per cent. there were strong reasons for suspecting its existence. My own figures, dealing with 101 cases, gave inherited syphilis in 70 or 69.3 per cent.

Other statistics might readily be quoted, but enough have been given to show that, broadly speaking adequate evidence of inherited syphilis may be obtained in about two-thirds of all cases of parenchymatous keratitis.

With regard to the frequency of tuberculous interstitial keratitis, some interesting figures have recently been published by H. Rabiger (ref. in *Archives of Ophthalmology*, November, 1907, p. 875). In 349 cases of keratitis observed at the University Polyclinic at Berlin, tuberculosis was found with certainty in 11 per cent., and with probability in 9.7 per cent.—total, 20.7 per cent. In my own series of 101 cases tuberculosis was identified as the cause of the keratitis in 10—that is, in 9.90 per cent. The more extended employment of Calmette's serum test will doubtless help us to recognise such cases with more certainty.

It would appear that interstitial keratitis is by no means rare as a late, tertiary consequence of acquired syphilis. The connection was first mentioned by Velpeau in 1840 (" Maladie des Yeux,") and was described in 1861 by Follin (*Pathologie Externe*, T. I., p. 708, 1861)—that is to say, two years before the publication of Hutchinson's famous memoir, in which he commented on " the entire absence of interstitial keratitis from the *rôle* of tertiary symptoms of acquired syphilis " (*loco. citato.*, p. 221). In a later work (" Syphilis," 1889, p. 237), however, Hutchinson modified this view, and recognised the possibility of an acquired interstitial keratitis.

According to figures collected by Pfister from Professor Haab's klinik (*loco citato*), of 130 cases of keratitis 3.8 per cent. (2.3 per cent. certain and 1.5 per cent. somewhat doubtful) were due to the acquired disorder, while Ancke (*Centralb. f. prak. Augenheilkunde*, 1885, p. 360) found the proportion in 100 cases to be as high as 10 per cent. Among my series of 101 cases of parenchymatous keratitis, 4, or 3.96 per cent. were unquestionably due to acquired syphilis.

(a) A contribution to the discussion on Inherited Syphilis, at the Society for the Study of Disease in Children, on December 18th, 1907.

It is important to note that such cases have been met with, even in children. For example, Mauthner (Zeissl's *Lehrbuch der Syphilis* p. 279) saw a case of interstitial keratitis in a suckling that had contracted syphilis from its nurse. Moreover, Trousseau (*Annales d'oculistique*, September, 1895, p. 206) has mentioned the case of a boy, æt. 8, who was infected by his nurse with syphilis. The result was a very severe attack of bilateral keratitis. Lastly, I reported a case of the kind (*The Ophthalmoscope*, Vol. I., 1903, p. 169) in a girl, æt. 12, who had suffered from a chancre on one upper eyelid two or three months after birth.

It may be noted as an interesting point that quite a number of cases of interstitial keratitis have been known to follow an indurated chancre on the eyelid or conjunctiva.

The name "interstitial keratitis" is good in so far as it directs attention to a prominent feature of the malady—namely, to opacities "like microscopic masses of fog," situated at various levels in the substance of the cornea. It suggests, nevertheless, a mistaken view as to the pathology of the condition (Fuchs, v. Hipple, Pfluger, de Lapersonne, C. D. Marshal, Parsons, &c.). The available evidence indicates that the ailment is primarily an inflammation of the tissues of the ciliary body, which forms (as everybody knows) the middle part of the uveal tract, of which the other parts are the iris and the choroid. From the ciliary body inflammation spreads forwards to the iris as well as to the deeper layers of the cornea, and backwards to the anterior parts of the choroid. Keratitis and the commonly associated choroiditis and iritis, therefore, are, strictly speaking, conditions secondary to an inflammation of the ciliary body. The underlying process may conveniently and accurately be described by the expression "anterior uveitis."

If this view be not grasped, it becomes difficult to understand some clinical features of the disease. For example, in my experience, it is not very uncommon for the ailment to begin with what appears to be an accumulation of pus in the anterior chamber of the inflamed eye (*a*). This hypopyon, of course, represents an exudation from the inflamed ciliary body, which has passed through the pupil and has thereby gained the anterior chamber. Another early sign is the existence of deposits on Descemet's membrane, the "aquo-capsulitis" of the older, and the "keratitis punctata" of the more modern, writers, and this, again, is to be regarded as the expression of an exudation from the ciliary body. The occasional bleeding into the anterior chamber (hyperæmia), which may usher in an attack of parenchymatous keratitis, is almost certainly due to the rupture of some small distended vessel in the ciliary body. None of these appearances can be explained on the theory that the disease is primarily one of the cornea.

Further, the iritis which often precedes or accompanies the keratitis can be best accounted for by an extension forwards from an inflamed ciliary body.

A similar remark applies equally to the choroiditis which is frequently found when the cornea has cleared enough to allow of an examination of the fundus with the ophthalmoscope. In cases where choroiditis is known to precede by months or years the development of keratitis, the backward extension to the choroid has antedated the forward extension to the cornea, or has possibly occurred independently of the ciliary inflammation. Cases of this type are sometimes of an unusually severe type. The following is an example: John O——, æt. 8, first seen on January 5th, 1893. A typically syphilitic subject, with "bossy" forehead, rhagades, and dwarfed and notched upper central incisors, and a tendency to ptosis. Sight equalled about one-fifth of the normal, as the result of widely-spread, bilateral choroido-retinitis. In September, 1893, the right eye developed interstitial keratitis, and seven months later (April 25th, 1894) the left eye followed suit. On May 30th each knee-joint became distended with fluid. The corneæ presented a peculiar appearance, since an irregular area towards the centre, 5 mm. at its widest part, resembled damp wash-leather, and was everywhere surrounded by a zone of plum-coloured vascular tissue—a confluent "salmon patch," in short. Viewed from the side, the cornea projected forward cone-wise, the blunt apex of the cone being formed by opaque cornea and its sides by the vascular patch. By this time the lad had become somewhat deaf, without discharge from the ears. On June 19th, a portion of the grey opaque central area had exfoliated. Deafness was increasing. Both ankles had become swollen. In August, 1894, the lad developed delusions, which became very pronounced towards the end of that month. He used vile language, insisted upon getting out of bed for the express purpose of breaking the windows of the ward or, for that matter, anything else he could grope his way to, for by this time he was, to all intents and purposes, blind. John O——,was then transferred from the Ophthalmic School to another institution, where "he developed most acute mania, and had delusions that people were coming to kill him and that there were bloodhounds in the cupboard." In 1902—that is, nine years after I first saw him—the patient was an inmate of Darenth Asylum, quite blind, and suffering from imbecility with occassional attacks of excitement. One of his eyes had been removed owing to an injury.

The case just described presented several peculiarities, and amongst them ulceration of one cornea. This complication, in my experience, is not common. For instance, among my 97 cases (*a*) of interstitial keratitis it occurred in 4—that is to say, in 4.12 per cent. That it might occur was known to Hutchinson, who alluded to one or two cases on page 29, of his oft-quoted memoir. W. Spencer Watson (*Ophthalmic Hospital Reports*, Vol. IV., p. 296), writing a few years after Hutchinson, reported an instance of unilateral ulceration observed in a series of twenty-five cases of interstitial keratitis, R. Ancke (*Centralb. f. prak. Augenheilkunde*, 1885, p. 296) had one example of ulceration among 100 cases of interstitial keratitis. E. T. Collins (*Ophthalmic Hospital Reports*, Vol. XI., 1887), described four cases in corneæ which showed extreme vascularity, and in which a small central island of non-vascular tissue was alone left. This islet became yellow and then ulcerated. In one of Collins' cases there was perforation, but cicatrisation took place in the other three. His patients showed unmistakable signs of inherited syphilis, either in the teeth or the physiognomy.

In a majority of cases of parenchymatous keratitis, one cornea is first attacked and the other cornea, according to Hutchinson (*loco citato*, p. 29), "after from one to two months." But it should be borne in mind that the interval may be and often is much longer than this. The extreme instance reported by Consiglio (*Beitrage z. Augenheilkunde*, May, 1905), where the interval amounted to twenty-six years, must be almost unique, although in his case the evidence of inherited syphilis was not altogether conclusive. My own series includes one case where the interval amounted to about seven years, The facts follow:—Edmund D——, æt. 13, seen on December 22nd, 1899, with early interstitial keratitis affecting the right eye, which had been divergent since infancy. After making a nearly complete recovery, the right eye relapsed in September, 1905. On November 30th, 1906, the following note was made: "The left eye has been affected for the last fortnight—*i.e.*, there has been an interval of seven years between the attacks in the two eyes. The patient is deaf and his teeth are typical of inherited syphilis. Hutchinson's triad is therefore present."

All observers agree that parenchymatous keratitis is essentially a disease of childhood. On this point there is no difference of opinion. It is, nevertheless, relatively rare in very young children, and equally so after mature age has been reached. Hutchinson, for example, had never witnessed its occurrence earlier than two years or later than twenty-six years. It is most frequent between the ages of five and eighteen

---

(*a*) Hypopyon was present in many of my 101 cases of Interstitial Keratitis.

(*a*) Four cases due to acquired syphilis omitted.

years (Hutchinson), or of six and fifteen years (Nettleship).

The age-incidence of my 97 cases, arranged in quinquennial periods, comes out as follows :—

Period.	Number.	Percentage.
1 to 5 years	6	6.19
5 to 10 ,,	38	39.18
10 to 15 ,,	26	26.80
15 to 20 ,,	14	14.43
20 to 25 ,,	8	8.25
25 to 30 ,,	2	2.06
Over 30 ,,	3	3.09

An inspection of the foregoing figures will at once show that of my 97 cases, four-fifths, or 80.41 per cent., occurred between the ages of 5 and 15 years. My series includes one case in a woman, æt. 36, whose syphilitic inheritance was attested by notched upper central incisors, rhagades at angles of the mouth, and by a node on the frontal bone, one inch above the inner end of the left eyebrow. R. Marcus Gunn (*The Polyclinic*, December, 1902) reported a case in a patient, æt. 36 ; Pfister, (*loco citato*) in a man æt. 37½ ; and Greeff (*loco citato*, p. 13) in a man of 38 years.

The rule that syphilitic parenchymatous keratitis is relatively commoner in females than in males, is supported by an analysis of my own cases, 97 in number. Of the total, 37 (38.14 per cent.) were in males, and 60 (61.86 per cent.) in females. It is, perhaps worth noting, that the same curious disproportion between males and females applies also to juvenile tabes dorsalis. Thus, Cantonnet (*Archives d'ophthalmologie*, November, 1907), as the result of an analysis of 88 cases, found that females were affected in 63.6 per cent, and males in 37.3 per cent.

It should be noted that the figures given by Baker and Story (*Ophthalmic Review*, November, 1885), and by Ancke (*Centralbl. f. prak. Augenheilkunde*, 1885, p. 360) respectively form an exception to the general experience as to the age-incidence of keratitis, as stated above.

The discovery of the specific cause of syphilis in the shape of the treponema pallidum, together with the possibility of inoculating apes, rabbits (*a*) and dogs with the virus, has widened our conception of the morbid processes that lead up to the development of interstitial keratitis. The disease in question has been produced experimentally in certain animals by the implantation of syphilitic products. Indeed, prior to the discovery of the treponema, P. Salmon (ref. in *Archives d'ophtalmologie*, April, 1905, p. 1623) observed iritis and keratitis thirty-three days after a monkey had been inoculated with a syphilitic papule from man.

We know that the tissues and organs of the syphilitic fœtus or baby are literally flooded with the treponema, large numbers of which have been found in the placenta, the umbilical cord, the blood of the umbilical vein, and especially the liver. The organisms that escape the liver are distributed by the fœtal circulation to every part of the body, where they determine this or that syphilitic lesion. The treponema has been found in cutaneous lesions, as pemphigus, by Levaditi and others, in perioral ulcerations by Elizaldi and Wernicke, in glandular lesions by Panea and Babes. That is by no means all, for apart from definite lesions such as those named, the treponema had been found in every internal organ so far examined with the microscope. As regards the eye, the findings from our present point of view are highly suggestive. Thus, Hans Bab (*Deutsche Med. Wochenschrift*, November 29th, 1906) examined the eyes of three specific still-born babies. Preparations were treated by the silver impregnation method, and large numbers of the spirochætes were found in all the tissues of the eye, with the exception of the vitreous humour and the crystalline lens. It is important to note that the cornea contained a large number of the organisms. Again, H. Schlimpert (*Ibid*, 1906, p. 1942) succeeded in discovering the treponema in various parts of the eyes of syphilitic fœtuses. Lastly, spirochætes have been demonstrated in the tissues of seemingly unaffected eyes of syphilitic fœtuses and babies by some other observers, including Peters, Gierke and Stock and myself.

It would thus seem probable that if the child survive, these micro-organisms (possibly in some different morphological form) lie dormant in the tissues of the eye, more especially in the ciliary body and the cornea, They cause no mischief until some exciting cause, of a local or general nature, lowers the resistance of the part, and allows the treponema to come into action. The result is an attack of interstitial keratitis.

In this view we can explain an observation made by many surgeons—namely, that a slight injury to the eye may precipitate an attack of parenchymatous keratitis. I well remember the first case of this kind that happened in my practice. A girl, æt. 11, was admitted to the Ophthalmic School, Hanwell, for trachoma, pannus, and lead opacities of each cornea, in consequence of which the child was almost blind. Her syphilitic diathesis was attested by (1) notched central incisors of the upper jaw ; (2) scars radiating from the mouth, the so-called " Fournier's cicatrices"; (3) " epithelial denudations " (*a*) about the skin of the upper lip and nose ; (4) slightly enlarged lymphatic glands ; and (5) cicatrices about the anus and buttocks, the so-called " Parrot's cicatrices." On March 16th, 1897, under cocaine, the metallic incrustations were more or less scraped away from the right cornea by means of a small, sharp scoop. The little operation, somewhat to my surprise, was followed by redness of the eye, and by increased haziness and vascularity of the cornea—in a word, by the clinical appearances of an ordinary parenchymatous keratitis. On May 4th —that is, forty-nine days after the operation—the condition was typical of interstitial keratitis. In view of etiology, the case was an interesting one, and so on June 16th, the operation was repeated on the other eye. I am bound to add that the second intervention was not followed by interstitial inflammation. Be that as it may, the association between slight injury to the eye, on the one hand, and parenchymatous inflammation, on the other, is far from uncommon, as will be obvious from the fact that I possess notes of fifteen such cases.

Interstitial keratitis may supervene during the course of illnesses, such as influenza and typhoid fever. Here are one or two cases in point :—

Ellen W., æt. 11, was admitted to the North-Eastern Hospital for Children under my colleague, Dr. James Taylor, on account of typhoid fever. On the seventeenth day of the fever (approximately) the left pupil was noticed to be contracted and the cornea of the left eye rather dull. When seen by me five days later, there could be no doubt that the case was one of parenchymatous keratitis. The girl had suffered from periostitis of the right tibia for several weeks. Three months after the first eye had been attacked, the other cornea went through a much milder attack of keratitis. Florence G——, æt. 8, a child who presented rhagades at the angles of the mouth, a *café au lait* complexion, and suspicious incisor and molar teeth, in addition to slight deafness, was brought to the Evelina Hospital on March 15th, 1905, for a relapsed interstitial keratitis of her right eye. The history was to the effect that three years before, about a fortnight after her discharge from an Asylums Board Hospital, where she had spent three months on account of enteric fever, both eyes became inflamed, one soon after the other. The condition had slowly improved until a relapse a few weeks before the child was brought to me.

I have also seen interstitial keratitis follow a whitlow so closely as to suggest a connection between the two affections.

It is now, I think, generally recognised that interstitial keratitis may relapse—or, more correctly,

---

(a) As long ago as 1881 Paul Haensell (v. Graefe's *Archiv. f. Ophtalmologie*, XXVII, III, p. 93) showed that syphilitic virus could be successfully inoculated into the iris and cornea of the rabbit.

(a) The expression "epithelial denudation" I apply to those superficial cicatrices, whose favourite site is at the junction of the ala nasi with the upper lip. Their significance and diagnostic value is the same as Fournier's cicatrices.

recur—in one and the same patient. Manasse, in 50 cases had 8 recurrences, or 16 per cent., and v. Hippel, among 87 cases, 15 recurrences, or 17.25 per cent. The proportion in my own cases, many of which remained under observation for long periods of time, was somewhat higher, namely, 22 per cent. As to the explanation of recurrences we must assume that spirochætes have remained dormant in the tissues of the cornea as a sequel of the primary attack. I believe that recurrences are commoner in cases originally treated without than with mercury, and I am confident that, as a rule, they are more difficult to manage than that original attack.

Experimental Keratitis.—Bertarelli (*Presse Médicale*, August 22nd, 1906) obtained a positive result by inoculating the cornea of rabbits with an emulsion of human chancres. The animals' corneæ showed numerous spirochætes, and, in addition, a pronounced leucocytic infiltration, which extended into the seemingly unaffected parts of the cornea. Scherber and v. Benedek (*Munch. Med. Wochenschrift*, June 14th, 1906) produced nodular iritis and interstitial keratitis by inoculating the anterior chamber of rabbits with syphilitic virus. Most suggestive experiments were reported during the course of 1906 by Greeff and Clausen (*Bericht der Oph. Gesellschaft*, Heidelberg, 1906), who inoculated the eyes of apes and rabbits with syphilitic material, and after the lapse of some weeks, observed the development of a kind of parenchymatous keratitis. In the earlier cases, numerous spirochætes could be demonstrated, but the organism could not be found in the more advanced cases. The authors concluded that the corneal opacity was the outcome of a leucocytic invasion, which attacked and eventually destroyed the micro-parasite.

In a second communication (*Deutsche Med. Wochenschrift*, 1906, No. 36), Greeff and Clausen concluded that the pathogenic agents of syphilis multiplied in the cornea, and thus caused an invasion by leucocytes, which finally exterminated the micro-organisms. Lastly, Hoffmann and Bruening (*Deutsche Med. Wochenschrift* April 4, 1907) produced keratitis by the inoculation of a rabbit's eye with a morsel of a human chancre, and obtained a somewhat similar result when an emulsified chancre was introduced into the anterior chamber. Smears from the diseased cornea, when stained by Giemsa's method, showed the spirochæta pallida, thereby proving the essentially syphilitic nature of the keratitis.

Panas (*Archives d'ophtalmologie*, 1871, p. 577) taught that interstitial keratitis was a dystrophic symptom, the indirect cause of which was to be sought, not only in ancestral syphilis but also in lymphatism, scrofula, gout, and arthritism. It is now suggested, mainly as the result of experimental and histological researches, that it is, in reality, an infection of the tissues of the cornea with this or that specific organism, the most important of such being the treponema pallidum, the tubercle bacillus, the B. influenzæ, the plasmodium malariæ, and the parasite of trypanosomiasis.

In brief, it can nowadays scarcely be doubted that syphilitic interstitial keratitis is due to the presence in the parenchyma of the cornea of the causal agent of syphilis. The treponema, however, has yet to be demonstrated in that structure. The hiatus on this vital point is not to be wondered at, since eyes are seldom, if ever, removed during the height of parenchymatous keratitis, nor do patients usually die during the course of that affection. Speaking for myself, I have failed to find the spirochæte in scrapings from eyes affected with keratitis; but, then, superficial parts only were removed. Despite the known difficulty of recognising the treponema in tertiary syphilitic lesions, it is safe to predict that sooner or later the organism will be discovered in the tissues of the cornea. The chain of evidence, which still lacks one link, will then be complete.

Aphorisms Respecting Interstitial Keratitis.

1. Interstitial keratitis is not a primary affection of the cornea, but is probably in every instance secondary to changes in the anterior part of the uveal tract.
2. The disease is nearly twice as frequent in females as in males.
3. Four-fifths of the cases occur between the ages of five and fifteen years.
4. The disease can be shown in about two-thirds of all cases to be associated with signs of inherited syphilis, of which the commonest are the dental, facial, and ocular stigmata. Other important causes of the disease are tuberculosis, acquired syphilis, influenza, malaria, and sleeping sickness.
5. Given a predisposing cause, the affection may be excited by almost anything that lowers resistance, local or general.
6. Ulceration of the cornea occurs in a notable percentage of all cases.
7. The ailment is bilateral in three-fourths of the cases. The interval between the two eyes being attacked may, however, run into several years.
8. Recurrences occur in perhaps one-fifth of the cases, are commoner in cases treated without than with mercury, and are often very difficult to manage.
9. The disease is due to the lodgment and multiplication in the cornea of the treponema pallidum derived primarily from the uveal tract.
10. Interstitial keratitis does not form more than 1 per cent. of the cases met with in a special department for diseases of the eye.

ON EYE STRAIN. (a)

By HERBERT C. MOONEY, B.Ch., F.R.C.S.,

Ophthalmic Surgeon to the Children's Hospital, Dublin.

In the short paper which I am about to read to you, I have brought together some symptoms of neuroses which one meets with in eye work, and which, although varying very much in their severity and distribution, are generally grouped under the term "Eye Strain."

Although it is a long time since Donders described the errors of refraction of the eye, and since Weir Mitchell wrote articles in which he brought forward the part played by the eye as a cause of headaches, yet it would appear that the relation which errors of refraction bear to headaches and other neuroses is not as generally appreciated as it should be.

When we consider the condition of affairs when the eye is provided with an imperfect refractive system, it is not surprising that some evil results therefrom. Take the simplest case, that of hypermetropia. Here, in order that the retina may be provided with perfect images the ciliary muscle must be kept in a constant state of tension from morning till night. With the exception of the circulation and respiration, is any other system expected to do as much? Even the stomach, which stands a fair amount of ill-treatment, breaks down, I believe, when subjected to a constant call on its functions. When the refractive error is one of astigmatism we have a stronger reason for nervous exhaustion, for in this case there is an inequality in the refraction of the principal meridians of the eye, with a result that the images presented to the retina for its elaboration are not alone blurred, but they are also distorted images of the object looked at. No effort on the part of the ciliary muscle can correct this condition completely, whatever it may accomplish in reducing the distortion, so that the work of the retinal elements and the visual act as a whole is considerably increased, with a resulting fatigue somewhere.

Many patients who complain of headaches will not believe that their eyes have anything to do with the trouble, because they are satisfied (and rightly so) that they can see as well as the best. A patient of mine, a Queenslander, complained of headaches. Without glasses the vision of each eye came up to our normal standard. With corrective cylinders of ÷ 1 D this acuity of vision equalled 5 / 2.5—*i.e.*, twice as good as the accepted standard. But it must be remembered the visual act is not con-

---

(a) Read at the Medical Section of the Royal Academy of Medicine in Ireland, December 6th, 1907.

fined to focussing images on the retina. There is the fusion of these images of the two eyes to be accomplished by the six pairs of extrinsic muscles. So that, with two emmetropic eyes and a complete accommodative system, we may have some irregularity or want of symmetrical action between the various pairs of the extrinsic muscles. Those which are concerned most with vision for different distances are the lateral recti, and these are the muscles which we find most at fault. But even these recti may possess a moderate degree of a symmetrical action without producing symptoms, but a very small degree of defect in the action of the elevators or depressors of the globe usually produces a discomfort of a marked degree, and is often the cause of the most distinct symptoms of eye strain. Having thus briefly viewed the possibility of the intrinsic or extrinsic muscles, acting individually, being a cause of strain, or asthenopia, we must recognise that when they come to work together in cases where there are not only errors of refraction, but errors of different kinds in the two eyes, the source for eye strain is much widened. It is in cases of marked difference in the refraction of the two eyes, or want of balance in the extrinsic muscles, that we find cases of migraine occurring which are relieved by glasses.

Now to refer to the symptoms associated with eye strain. Of these headache is the most common. The pain may be across the forehead or at the root of the nose. It is usually bilateral, or may affect one side of the forehead or one temple. The pain may be referred to the vertex, a not uncommon site, or more rarely to the occiput. The pain varies very much in character, from being a constant dull ache to one which may be described as darting or neuralgic in character. The headache may be constant or intermittent, or noticed only when the eyes are applied to close work or, perhaps, may have no relation to the amount of near work performed.

In addition to the headache the patient may complain of apathy, giddiness, and sleeplessness.

The gastric symptoms sometimes met with take various forms, ranging from slight dyspeptic symptoms to nausea and vomiting. I am not anxious to work out the reflex path in such cases as these, but there would seem to be a connection between the nerves of the eye and the pneumogastric, for in cases of acute glaucoma, where pain and vomiting are the prominent symptoms, the real cause of the trouble may be overlooked, and a bilious attack diagnosed, with rather bad results to the vision of the affected eye. I have seen a very weak solution of eserin act sufficiently on the ciliary muscle to produce such giddiness and nausea, that the patient had to remain lying down for about six hours.

As already mentioned, migraine, with all its typical train of symptoms, is capable of being relieved, if not cured, by the suitable corrective lenses. These cases are usually found where the error of refraction is in one eye only, or where it differs in the two eyes From my own experience I am satisfied that I have seen cases of migraine relieved by the use of glasses. What I mean by relieved is, that the attacks become much less frequent. In one case in particular, where the pain was migrainous, but there were no characteristic scotomata or blind spots, and in which the attacks were frequent (one every eight or ten days), the use of glasses for reading brought about a reduction of the number of attacks to about one every month or six weeks, although the refractive error was very marked and differed in the two eyes, this lady would not wear her glasses constantly, as, of course, she should have done.

Children, as a rule, do not complain of headache, but they very often have hypermetropia or some form of astigmatism imprinted on their eyelids, as for example sties, chronic conjunctivitis and blepharitis, twitching and blinking of the lids. I have had an opportunity of seeing a good number of cases of ocular headache amongst the boys of one of our large schools. Their ages varied from 11 or 12 to 14 or 15, and their grievance was that the incandescent gas was too bright. Well, nearly all these cases, 9 per cent. of the whole school, had one form of astigmatism or another, so that I do not consider the quality or quantity of the illuminant had so much to do with the headaches as the astigmatism. I may remark here that I believe many of those who wear coloured or smoked glasses (in the absence of inflammatory affections of the eye, of course) would be able to discard the disfiguring glasses if they had their astigmatism corrected, for even the low degrees of astigmatism will produce an irritability or hyperæsthesia of the retina which renders the eye intolerant of ordinary diffuse day light.

As to treatment, I need not go into minutiæ. Suffice it to say, that each case must be carefully and deliberately examined by the various methods at our disposal, not refraining from the use of atropine or homatropine in certain cases. The routine testing of the balance of the extrinsic muscles with Maddox's rod and prisms should be adopted, for I have mentioned that the refraction of the eye may be quite normal, but the muscle balance faulty. It is well not to ignore the small degrees of astigmatism, such as .25D., for much may be done by the wearing of the weakest cylinders.

In conclusion, I would like to warn you against being put off your guard by the patient who wears glasses, who may complain of headache, telling you that his glasses are right because ordered by an experienced oculist. Very often in ordering cylinders it is right not to give the full correction, and such glasses will afford relief for two or three years, perhaps, but then the patient may have a return of his headaches, which will be probably cured by ordering the full cylindrical correction. In young persons the amount and axis of astigmatism are liable to alter, and, finally, persons who do not wear their glasses horizontally in front of their eyes are liable to produce symptoms of eye strain, although the glasses themselves may be quite correct.

When Dr. Oliver, of Philadelphia, wrote that asthenopia is the bane of the civilised minority, I think he was using strong language, but perhaps I have said a little towards justifying it.

THE EFFECTS OF THE RONTGEN RAYS ON LYMPHATICS AND MYELOID LEUKÆMIA.

By DR. EMIL EPSTEIN.

Poliklinik, Vienna.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

IN discussing the Röntgen rays, it is necessary to explain the methods we practice in the Kienböck clinic, where such a wealth of material is to be found all the year round. The present remarks will be directed towards the hæmatic system, particularly four cases of leucocythemia, and the influence of the rays on this pathological tissue.

Native preparations are made from the blood of each patient, and the hæmoglobin measured by Fleishl instrument, while the corpuscles are analysed and carefully counted according to Turk's method given in his clinical hæmatology. The greatest difficulty we have is the selection of an eosin solution, as so many of these are now in use, all having individual advantages of their own. In the Kienböck clinic we have selected Zollikopfer's solution as a more stable fluid.

We use Müller's tubes, as prepared by Reimyer, Gebbert, Shull, etc. The rays have three measurements :—(1) The strength of the ray; (2) the radiometric measurement according to Sabourand-Noiré; and thirdly, the radiographic method adopted by Kienböck of quantimeter. The two latter are purely control measurements to prevent over-dosage by the first, and thus avert burning. Every sitting has a normal dose administered, *i.e.*, the maximal dose of Sabourand-Noiré, or 10 on Kienböck's quantimeter. The secondary current is between 4 and 5 deci-milliamperes, and the focus between 17 and 20 centimetres, or 7.87 inches. After receiving a dose of this kind the rays would not be applied for a month afterwards. To avoid misunderstandings in the descriptions, it might be noted here that Turk's terminology has been adopted.

Case I.—A merchant, æt. 44, whose mother was always healthy and lived eighty-four years, but father died earlier of inflammation of bowel. As far as the patient recollects, he was in good health till March, 1905, when he took middle ear inflammation, for which he was operated on. After this swellings commenced in the glands of the neck, some of which broke and discharged. Lues and potus negative.

When received into hospital, on June 13th, 1906, the patient was feeble, white, and emaciated. The cerebral nerves were normal, pupil moderately dilated, and reaction prompt. The glands in the region of the neck on both sides were about the size of beans, hard, and mobile. The right supra-clavicular glands were the largest, while the left sterno-cleido muscle was hard with infiltration, over which ran a red inflamed line 5 centimetres long and 2 broad, with a granulating ulcer and surrounding ulceration. This was in the region of the beans on both sides, but movable, while those of the axilla were larger, particularly the left side, and as hard as stones. On the other hand, those of the cubitals were not enlarged. The inguinals, however, were large and hard, but could be moved in the direction of the lymph ducts, while those on the inside of the leg and knee were the size of peas.

The spleen was very large, commencing at the normal line above, or ninth rib, and extending far beneath the ribs, and running forwards and internally to within two centimetres of the median line of the body below the level of the umbilicus. The heart was healthy and the lungs perfectly clear on percussion, though a few fine râles could be detected at the apex of the left.

On the first day of treatment the blood was examined, with the following result:—

Hæmoglobin by Fleischl's instrument, 65%
Number of red blood corpuscles, 4,900,000.
Colour index, 0.66.
Number of white blood corpuscles, 24,300.
Small lymphocytes, 19,400 = 79.9 %}
Large lymphocytes, 1,900 = 7.8 %} = 87.7%
Polynuclear leucocytes = 12.8%

After completing this examination, the rays were applied to the left leg on June 13th.

On June 15th the blood was again examined, with the following result:—

Number of white corpuscles, 24,400.
Small lymphocytes, 20,500 = 84.0 %}
Large lymphocytes, 960 = 3.9 %} = 87.9%
Polynuclear leucocytes, 2,930 = 12.0%

On this date the right leg was irradiated. On the 16th both thighs were done, and on the 18th the right arm.

On June 19th the blood was again examined:—

Total white corpuscles, 18,430.
Small lymphocytes, 13,070 = 70.9 %}
Large lymphocytes, 1,130 = 6.1 %} = 77.5%
Polynuclear leucocytes, 4,230 = 22.9%

On this date the right arm was irradiated.

On July 20th blood examined gave:—

White blood corpuscles, 9,860.
Lymphocytes, 7,630.
Small lymphocytes, 6,870 = 69.7 %}
Large lymphocytes, 760 = 7.8 %} = 77.5 %
Polynuclear leucocytes, 2,230 = 22.5%

On this date the right arm was exposed to the rays. The spleen was exposed on the 21st and 22nd, as well as the supra-clavicular glands on the latter rate, while the axillary glands were irradiated on the 23rd on both sides.

On June 25th the blood was again examined:—

Total white corpuscles, 9,130.
Small lymphocytes, 5,730 = 62.7 %}
Large lymphocytes, 800 = 8.7 %} = 71.4%
Polynuclear leucocytes, 2,600 = 28.8 %

The reddening over the left supra-clavicular region is reduced to 3½ centimetres, the infiltration less, and the ulcer healing.

On June 26th the inguinal glands were exposed. On June 27th the blood was examined:—

Total number of white corpuscles, 8,280.
Small lymphocytes, 5,570 = 67.2%}
Large lymphocytes, 880 = 10.6%} = 77.8%
Polynuclear leucocytes, 1,830 = 22.2%

About this period reddening and itching of the skin commenced, and the left hypochondrium was exposed. June 28th a fresh ulcer with infiltration apeared in the supra-clavicular space. June 30th the right hypochondrium was exposed with the anterior side of the liver. On July 2nd the spleen had receded to 5½ centimetres from the median line and ½ centimetre upwards. On July 2nd, 3rd, and 4th the lower bones of the legs were exposed.

July 6th the patient felt very unwell, and complained of sharp pains. The left supra- and infra-clavicular spaces were hard and tender, while the cervical and axillary glands are unchanged. Notwithstanding, both clavicular regions were exposed. On July 12th the left infiltrated supra-clavicular region began to discharge, but the axillary gland remained as before. June 19th the spleen was exposed in front and on the right; on the 20th the left was done, and repeated on the 21st. The ulceration of the infiltrated left supra-clavicular space was found healed on August 3rd. In the neck only a few of the glands could be found on the left side, while the right had a few hard glands about the size of beans. In both axillæ the glands were large.

The spleen from the beginning never exceeded its normal position upwards, but downwards and inwards was enormously increased at first, but was now greatly reduced. It was now a hand's breadth from the median line and four finger breadths below the ribs; the low pole was now on a level with the umbilicus. This viscus was again exposed on the 3rd: (*a*) Front, and (*b*) on the right side. The lower portion of the left leg was irradiated on the 4th, and the blood examined on August 6th:—

White corpuscles, 11,100.
Small leucocytes, 5,170 = 47 %}
Large leucocytes, 1,500 = 13.5%}
Polynuclear leucocytes, 4,430 = 40.3%

August 14th the right leg was irradiated, and on the following day two sittings were given to this limb; on the 16th both arms; on the 17th same limbs were repeated; and on the 18th the spleen was exposed fore and aft.

The patient was now allowed to go home and return in three months' time for further treatment. About the beginning of September, after he went home, he suffered from severe headache which did not keep him from sleeping, and disappeared about the end of the month. Subjectively at this time he felt much better.

On his return, November 13th, he appeared greatly improved, but the face still retained that yellowish-white colour that was present early in the disease, although it had now increased by a reddish infiltration; the pupils reacting promptly, cervical and supra-clavicular glands were less hard and more mobile; one of these lying over the cucularis was very tender. The skin everywhere over the glands was movable, and no ulceration as at the commencement. About the middle of the clavicle in the infra-clavicular space a few of the glands were very painful and swollen about the size of hazel-nuts, while those in the axillæ were the size of walnuts. In the upper third of the arm several were 2 centimetres long, spindle-shape, but not painful. The inguinal glands on both sides were about the size of beans; both lungs and heart were normal. The lower point of the spleen in the axilliary line was slightly below the costal arch and still tender.

On November 13th the examination of the blood gave the folowing:—

Hæmoglobin, Fleischl, 87%
White blood corpuscles, 8,660.
Small lymphocytes, 5,260 = 60.7%
Large lymphocytes, 3.4%
Polynuclear leucocytes, 3,110 = 35.9%
Transformation forms, 0.7%

After this followed another series of irradiations.

On November 14th the right cervical glands were exposed; on the 19th the left infra-clavicular glands were treated; on the 20th and 21st the inguinal glands, both left and right, were exposed. On November 22nd the blood gave:—

Total number of white blood corpuscles, 7,780.
Polynuclear leucocytes, 5,330 = 4.29%

After this examination the spleen was irradiated, and two hours after the sitting the blood examination gave:—

White blood corpuscles, 10,300.
Polynuclear leucocytes, 41%

The patient felt heavy and unwell after this exposure. On November 23rd the total number of

White blood corpuscles were 7,560.
Polynuclear leucocytes, 3,560 = 47%

The spleen was again irradiated for two days, but an unfortunate circumstance called the patient home suddenly, which prevented further treatment.

The diagnosis may now be conclusively stated as a case of benign chronic sublymphæmic lymphomatosis or pseudo-leukæmia, according to Pinkus. The supra-clavicular ulceration must be considered as a secondary infection, which was accompanied with great pain, infiltration, and abscess formation, succeeded by a rapid retrogression.

A NOTE ON

TUBERCULOSIS AS A FACTOR IN THE IRISH DEATH-RATE.

By W. R. MACDERMOTT, M.B.

In 1871, of 1,000 deaths occurring in Ireland, 156 were due to tuberculosis; we would therefore say that the disease as a factor of the mortality had the value 15.6 per cent. Again, taking the average for 35 years, 1871-1905 the same value was 14.9 per cent. But is this a true value—or, in other words, did tuberculosis determine the death-rate year by year? This may be put by asking whether the general rate and the part of it due to tuberculosis varied together, and in what way?

Tuberculosis being a principal cause of death, it might seem *à priori* that in any year a high mortality from it would correspond to a high general rate. There is certainly a relation between the variations of the two rates, but it is not so simple as this; the deviations of both from their means are different, both in magnitude and time. The highest death-rate in the 35 years is 20.0 (1879), the lowest 16.4 (1871); the highest tuberculosis rate is 16.1 (1899), the lowest 13.5 (1879). Contrary, therefore, to what might be expected, the lowest tuberculosis death-rate coincides with the highest general rate. In the ten years, 1871-80, the average G rate, as we will call it for brevity, is 18.3, and the average T rate 14.3; but the maximum T rate, 15.6, coincides with the minimum G rate, 16.4, and this is the rule for the twenty quantities to a significant extent.

In the next ten years the highest G rate, 19.2, coincides with the lowest T rate, 14.3; and the higher T rates, 15.4, 15.6, and 15.2, with the lower G rates. The same rule applies with but few exceptions for the last 15 years, 1891-1905, and to the whole period of 36 years; the G rate for the first ten years being 18.3, the T rate 14.3—they are for the last five years 17.6 and 15.7. The necessary inference to be drawn from the variations in detail is that the general death-rate falls as the part of it due to tuberculosis rises. The thing might be worked out more exactly by Karl Pearson's statistical methods, but anyone who glances at the figures in the last report of the Irish Registrar-General will think the problem itself sufficiently perplexing.

Tuberculosis in some of its manifestations is a very obscure affection, even under the conditions of the more refined means of diagnosis. There is, however, less liability to error where death is assigned to pulmonary phthisis. In the ten years 1871-80 the average yearly number of deaths was 96,674.5, of which 10,352.8 were due to phthisis. For the five years 1901-5 the corresponding numbers were 77,747.4 and 9,511.4. Thus, while the number of deaths declined by about 20 per cent., the number due to phthisis fell by only 8 per cent. Comparing the average for the five years with that for the 35 years 1871-1905, the fall is only 5 per cent. Thus a practically constant death-rate for phthisis has concurred with a fall of 20 per cent. in the total number of deaths. The variation from year to year of the phthisis rate is relatively very small compared with that of the general death-rate, but that of itself shows that the latter is not determined by it in proportion to the relative magnitude of the two rates. No matter whether the total number of deaths is 105,000 or 75,000, the number due to phthisis always remains somewhere about 10,000, and, of course, for this reason appears a minimum when the total is 105,000, and a maximum when it is 75,000. We cannot say that the variation in the total is due to a term falling under the total when that term remains very nearly a constant. Nor is it reasonable to conclude that what remains a constant under a vast variety of circumstances can be changed by means which may affect the true variable.

There are reasons, of course, why the number of deaths from phthisis remains constant relatively to the total as a variable, but it does not appear to me that there is any use at the present time in giving them. The position that the number is a constant is a statement of fact which is worth keeping to; it may be, of course, one applying only to Ireland. In general, however, if 10,000 deaths from phthisis occur, whether the total deaths are 105,000, 95,000, 85,000, or 75,000, it is evident that such number stated as a percentage of the total deaths is misleading. It is even more so stated as a percentage of the living, less the number dying in a year; both the general and phthisis mortality vary according to age distribution independently. I have not studied the remarkable fall which has occurred in the English death-rate from tuberculosis with sufficient care to venture any opinion on its nature and causes worth giving. It seems to me, however, that at no period can the English and Irish rates be compared except subject to corrections difficult or impossible to make. Registration of deaths did not come into operation in Ireland until 1864, and for ten years at least it was imperfect. Both in England and Ireland certification of death by medical men is imperfect, and in many cases impracticable. Judging, however, from intrinsic evidence, I believe the Irish statistics are more reliable than the English; the constancy of the Irish death-rate from phthisis is probably a fair indication of its exactitude.

In the last four decennia the English death-rate has fallen by 15 per cent., but by 33 per cent. for the age period 1-5. As the English population, 32,527,843, was constituted to the extent of 3,716,708 by those in that age-period, this means an accumulation of life in the higher age-periods which by mere increase of mass would give an apparent rise in the mortality occurring in them. But in the four decennia the tuberculosis rate fell by 38 per cent., a percentage not reflected in the general death-rate. The mortality from any cause is, *cæteris paribus*, as the mass it operates on. In England the mortality from phthisis has shifted in a remarkable manner to the higher age periods, and therefore is determined by a rapidly decreasing mass. Thus at 25 the mass would be 2,824,509, and at 45 1,573,188; so that, no other cause intervening, the maximum mortality in rising with age would diminish *pro rata* as the mass affected. In Ireland the age-period 25-35 gives a decided maximum; in England the maxima are given by 35-45 and 45-55, and therefore characterise a relatively much smaller mass. It is probable that, if this were taken into account, what is a constant for Ireland would appear also as a constant for England.

The Irish is predominantly a rural community, the English an urban. Concurring with a reduction of 38 per cent. in the tuberculosis death-rate, the purely rural English population has declined even more than the Irish—that is, the element in which the phthisis mortality is highest has greatly increased; that in which it is lowest decreased. The urban mortality in England is to the rural as the numbers 1,493 and 1,292. We are being told just now, or it is suggested to us, that the decline in the tuberculosis death-rate in England is due to improved sanitation, and, as usual, that country is set to us as an example. I am sufficiently well and long acquainted with it and Ireland to know that, though both are open to improvement in sanitary and other matters, the improvement that has actually occurred in both has been relatively much greater in the latter than in the former country. The assumption that the conditions of life of the rural Irishman are worse than that of the urban Englishman is one which should not be allowed to prejudice the consideration by medical men, at least, of difficult and complicated questions. Tuberculosis as a disease is one thing, as a cause of death another. So is scarlatina. The mortality from scarlatina has fallen in England in the proportion of 890 to 158, but the explanation of that is not that the disease has disappeared or that the infection has been "stamped out"—14,539 cases of it were treated in London hospitals alone in 1901—but that the disease is one thing in itself, another as a cause of death. The increased aggregation of the English people in great cities has favoured experience of the tuberculosis infection, but in all probability careful study and freedom from preconception would show that where tuberculosis, the disease or infection, is a maximum, the mortality from it is a minimum. The mortality is not as the disease, but as the susceptibility to it. In the present state of our knowledge, however, though the grounds for dissenting from the views expounded to uncritical audiences are clear, they do little more than suggest to us that the subject is one not adapted for popular exposition. It is admirable to give popular lectures on hygiene and sanitary science, but the pathology and causation of tuberculosis should be strictly kept as a preserve sacred to the professed votaries of Æsculapius.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Obstetrical and Gynæcological Section.

Meeting held Thursday, December 12th, 1907.

The President, Dr. Herbert Spencer, in the Chair.

THE SUPPORTS OF THE PELVIC VISCERA.

Dr. W. E. Fothergill read a paper on this subject.

The writer considers that the current teaching of gynæcological anatomy, while correct in a general sense, lacks that accuracy which is essential if the student is to have a real grip of his clinical work. It is generally assumed that the urino-genital organs are partly suspended by the so-called ligaments of the uterus, and partly supported from below by the pelvic floor. But the perinæum and the pelvic diaphragm are often seriously impaired by injury or loss of tone, without any consequent change in the position of the pelvic viscera, which shows that support from below is not essential. Again, during abdominal operations the ligaments of the uterus are seen to lie loose and slack upon the subjacent structures, and to have no supporting action whatever. The operation of vaginal hysterectomy affords confirmation of these observations, and reveals to the clinician the fact that the uterus is really supported by the sheaths of its blood-vessels, which attach it firmly to the sides of the pelvic diaphragm. In the same way the vagina and the bladder are held in position by the sheaths of their blood-vessels, the rectum having an independent attachment to the back of the pelvis. Thus lengthening and laxity of the sheaths of the blood-vessels is the one constant and essential factor in the causation of prolapse of the pelvic viscera.

The writer considers that while gynæcologists are well aware of these facts they refrain from teaching them, because they borrow their anatomical statements from the writings of professed anatomists. He therefore goes on to show, by quotation from recent papers by anatomists of the first rank, that descriptive anatomy has changed in a way exactly parallel to that in which clinical gynæcology has moved.

The uterosacral ligament is a mere peritoneal fold; the broad ligament is simply a mesosalpinx and mesovarium. The round ligament is a vestigial structure, the homologue of the gubernaculum testis, which pulls down the ovary and uterus in early fœtal life, and by no means supports them during post-natal life.

The superficial perineal muscles derived from the primitive sphincter cloacæ have a sphincteric and not a supporting action.

The muscles of the pelvic diaphragm are vestigial structures, being the degenerated representatives of the powerful tail-moving muscles of lower vertebrates. Their muscular action is largely lost; but, by virtue of their position, they, with their fascial coverings, form the funnel-shaped musculo-membranous structure known as the pelvic diaphragm. This could not support the plastic pelvic viscera, either by its shape or its muscularity, if the pelvic viscera were not firmly attached to its sides.

The conception of the pelvic fasciæ as independent and definite structures must be given up, and the fasciæ must be regarded simply as the connective tissue-coverings of the muscles, the viscera, and the blood-vessels.

The vessels and their sheaths, together with the ureters, nerves, and lymphatics, form masses of tissue which extend between the sides of the pelvis and the lateral aspects of the uterus, bladder, and vagina, and which hold these structures in position. The rectum is independently attached to the back of the pelvis, and lies loose in a channel between the vessels of the right and left sides. It is free from the urino-genital organs, and does not descend with them in prolapse unless the anterior rectal wall is pathologically adherent to the posterior vaginal wall.

The President (Dr. Herbert Spencer) thanked the author for the interesting and lucid communication he had brought before the Section. Although the question of the support of the pelvic viscera was one to be settled by anatomical research, anyone who had performed total abdominal hysterectomy and had noticed the "ligamentum transversale colli" which lay at a lower level than the uterine artery and was very dense in structure, would find it difficult to accept the statement that it was the sheath of the vessels which kept the uterus in place. Also how could the bladder be kept up by the sheath of the vessels which were small in number and size.

Dr. **Amand Routh** congratulated the author on his lucid and excellent discourse, and felt that it would be greatly to the advantage of both students and gynæcologists if the antiquated views so long held on the subject of the uterine supports were replaced by those now elaborated. He thought that the author had succeeded in proving his contention that the uterus was mainly supported by the perivascular connective tissue bundles above the pelvic floor. He had put into words much of the scepticism which gynæcologists have held as to the acceptance of the orthodox views. No one who is in the habit of opening the abdomen and of seeing the flaccid broad ligaments and the redundant circuitous round ligaments could hold the view that these structures support the uterus, whatever might be thought of the functions of the utero-sacral ligaments. He had long held the view that the connective tissue in the bases of the broad ligament and utero-sacral folds (which really unite and form one common connective tissue bundle at their junction with the supra-vaginal cervix) were very important agents in holding down the uterus to the floor of the pelvis. If in amputating the cervix per vaginam, these bundles are cut through, the freed uterine body can not only be easily drawn downwards by traction, but will be spontaneously elevated behind the pubes, if not held down by vulsella forceps. He thought, therefore, that the bundles of connective tissue grouped round the vessels and the ureters served rather as anchors to fix the uterus down to the pelvic diaphragm, preventing undue mobility both upwards and downwards. The normal anteversion of the uterus is doubtless maintained, according to Dr. Fothergill's views, by the perivascular sheaths suspending the supra-vaginal cervix from a direction upwards and backwards (in the erect position) much in the same way as the utero-sacral folds have been hitherto supposed to act. He hoped Dr. Fothergill's views would receive general attention and acceptance.

Dr. R. H. **Paramore** disagreed with what had been said by the author of the paper. In determining the position of the uterus and the maintenance of this position in the pelvis we had to consider not only the structures which united the uterus to the pelvic wall and the pelvic floor itself, but also the intra-abdominal pressure which had a definite influence upon the position of the pelvic viscera. The intra-abdominal pressure depended upon the capacity of the abdomen, the volume of the abdominal contents, and upon the condition of contraction of the muscles which enclose and form its boundaries. Dr. Matthews Duncan had laid stress on the retentive power of the abdomen, and drawn attention to the fact that the uterus does not alter its position as a result of complete rupture of the perinæum alone, but if prolapse occurred, other factors had come into play. In women with an undamaged pelvic floor, and in whom the intra-abdominal pressure was much increased by a deposit of fat in the omentum or mesentery, the uterus was often found high up owing to the activity of the levator ani. If in such cases the pelvic floor was damaged by child-birth, an inevitable prolapse resulted.

Dr. **Briggs** believed that too much was attributed to ligaments. The muscular and tendinous and other fibrous tissues around a joint controlled its security and mobility, and produced its stiffness. The ligaments of the pelvic viscera were insignificant compared with the mass of the muscles and their fascia, the fibrous packing between, and the fibrous envelopes of the viscera and canals.

Sir **Arthur Macan** said that the importance of the pelvic connective tissue was pointed out years ago by W. A. Freund, and more recently a firm band in the lower part of the broad ligament at each side of the cervix had been differentiated by Kocks under the name "Pars cardinalis lig lati." The effect of taking away the support from below could often be observed clinically in cases where prolapse of the anterior vaginal wall followed rupture of the perinæum. As the vaginal wall prolapsed it drew the cervix downwards and forwards, which produced backward displacement of the fundus, and finally prolapse. Prolapse of the uterus is also met with in old women, due to senile atrophy of the pelvic connective tissue, removing the natural support of the pelvic organs. The strength of the support from below was, he thought, well shown by the resistance the pelvic floor offered to the expulsion of the child's head during labour.

The following specimens were shown:—

Dr. C. **Hubert Roberts**, "A cancerous uterus and glands removed by Wertheim's method."

Dr. **Peter Horrocks**, "Tuberculous disease of the cervix."

Dr. **James Oliver**, "A somewhat unique tubal gestation."

Dr. A. H. N. **Lewers**, "Sarcoma of the ovary complicated by carcinoma of the body of the uterus; operation."

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held December 13th, 1907.

Dr. **George E. Shuttleworth** in the Chair.

Mr. R. **Clement Lucas** opened a discussion on

INHERITED SYPHILIS.

This paper will be published in a future number.

Mr. **Sydney Stephenson's** communication was based upon an analysis of 101 cases of interstitial keratitis. Associated signs of inherited syphilis were present in 69.3 per cent., and of tubercle in 9.9 per cent. of the patients. The series included four examples of keratitis due to acquired syphilis, one of which was in a child, 12 years of age, who had suffered in infancy from a chancre of the eyelid; 61 per cent. of Mr. Stephenson's cases were in females, as against 38 per cent. in males. Four-fifths of the cases occurred between the ages of five and fifteen years, so that interstitial keratitis was essentially a disease of childhood, although cases had been met with at 38 years of age. The symptoms were apt to be atypical when the disease occurred in very young subjects. In one of Mr. Stephenson's patients an interval of seven years had elapsed before the second eye was attacked. Ulceration of the cornea had been noted in four of the author's cases. Stress was laid upon the influence as a determining factor of keratitis of any condition, local or general, capable of lowering the patient's resistance. The name "interstitial keratitis" did not correspond with the pathology of the condition, which was essentially one of inflammation of the ciliary body. An account was given of the experimental production of keratitis, caused in syphilitic cases by the lodgment and multiplication of the treponema pallidum in the tissues of the cornea.

Mr. **George Pernet** said he considered the features of importance in a discussion of this kind at the present moment were heredity and the treponema pallidum. As to heredity proper, we knew little about it. But he desired to emphasise the fact that the usual English designation, congenital syphilis, though not biologically correct, was preferable to the employment of the term hereditary syphilis of Continental writers. All the evidence available pointed to the fact that there was no congenital syphilis of the child without syphilis of the mother. The subject was a complex one to deal with in so short a time, but there were various reasons against the infection of the ovum by means of the spermatozoa, notwithstanding the experiments of Finger with the sperm of syphilitics, experiments which, by-the-bye, had not been confirmed by Erich Hoffmann. Mr. Pernet referred to a case mentioned by Jullien of a syphilitic man with supernumerary fingers who had infected his wife; she had borne a syphilitic child with supernumerary fingers. But the man's mistress gave birth to a perfectly healthy child, also with supernumerary fingers. There could be very little doubt as to the paternity here. It was known, too, that a man with florid syphilis did not necessarily infect his wife. Again, there could be no doubt that Colles's law was a law; the exception to it could not hold water, various conditions, such as pemphigus neonatorum, Jacquet's erytheme erosif, and so forth, having been taken erroneously for syphilis in the child. In conclusion, he desired to insist on the maternal origin of congenital syphilis, and on the reliability of the observations of Abraham Colles and of Baumes.

Dr. H. G. **Adamson** made some remarks on the

DIAGNOSIS OF THE SKIN ERUPTION OF CONGENITAL SYPHILIS.

This was a matter which did not receive the attention which its importance demanded, and errors were often made, especially in regard to certain common non-specific eruptions of the napkin region, which were frequently wrongly diagnosed as congenital syphilis, with obviously serious consequences. The eruptions which might be mistaken for those of syphilis were:—

(1) Streptococcic impetigo.
(2) Seborrhœic dermatitis.
(3) Simple infantile erythema (of Jacquet).

The speaker showed diagrams illustrating the features and distribution of the eruptions in congenital syphilis, and in these three types of simple eruptions.

Streptococcic impetigo produced red, raw areas, with phlyctenular margins in the flexures, or occupying the whole napkin area, with crusted or bullous lesions on other parts.

Seborrhœic dermatitis also attacked the flexures (or the whole napkin region), and the areas had a yellowish red, granular surface. The eruption was associated with seborrhœa capitis in the child and in the mother.

Simple erythema, on the other hand, attacked the prominent convex surfaces of the napkin region, of the calves and of the heels in a marked manner, leaving out the flexures. There were three stages:—

(*a*) Erythematous; (*b*) papulo-erosive; (*c*) ulcerating.

The two latter were especially liable to be confused with syphilitic eruptions, but were distinguished by their affecting only prominent convex surfaces and by absence of other signs of syphilis. The syphilitic eruptions were characterised by disc-like coppery red patches, which might be erythematous, papular, scaly or crusted, and which attacked both flexures and prominent surfaces alike. A special point was that the palms and soles were the seat of these lesions. Other symptoms of syphilis were often present—namely, fissured lips, mucous patches at the anus, snuffles, hoarse cry, and muddy complexion.

Mr. A. H. **Tubby** discussed the

BONE AND JOINT LESIONS IN INHERITED SYPHILIS.

The cranial signs might be localised or general. Local manifestations took the form of bosses which were most marked on the frontal bone. The enlargement of the parietal eminences might exist alone or in conjunction with enlargement of the frontal eminences. Excessive overgrowth of the external occipital protuberance occurred occasionally, but it was a rare condition. The most striking of the lesions in the long bones was that producing syphilitic pseudo-paralysis. It occurred in infants before the fourth month, usually during the second month. The limb became useless, and then a swelling appeared in the neighbourhood of the epiphysis, associated with effusion into the neighbouring joint. Separation of the epiphysis might occur, and pus might form with necrosis of the entire epiphysis.

Dr. **George Carpenter** said that chronic snuffles was not always self-evident, and that it was important to recognise a postrhinal form with discharge by the posterior nares. Craniotabes was, he said, most usual in the second and third months of life, and whenever he detected it, the probability of syphilis occurred to him. Craniotabes was not a rickety manifestation, and Parrot's nodes were evidence of syphilis, not of rickets. He did not believe that syphilis produced rickets. During the first six months the majority of enlarged spleens were syphilitic. From the ninth to the thirtieth month, the rickety age of life, some cases were syphilitic, others could not be explained in that way, and although cases of spleno-megaly did arise in rickety children, they occurred infrequently, and spleno-megaly was a coincidence, not a symptom. Of syphilitic nephritis in infants he gave examples, and pointed out that on several occasions he had been able to diagnose the condition during life. He said that all cases of cirrhotic kidneys were not syphilitic, that in some cases the disease commenced in intra-uterine life, and that the contracted granular kidneys of children and adults could be of either syphilitic or simple, and certainly of infantile origin.

Dr. **Leonard Guthrie** sad that there were two kinds of nephritis attributed to inherited syphilis—acute and chronic. Both were essentially interstitial in character, though in both parenchymatous conditions might be present. Acute interstitial nephritis was sometimes congential, or occurred shortly after birth in undoubtedly syphilitic infants. The symptoms were usually gastro-intestinal at first, and ended in uræmia; œdema was rare in purely interstitial nephritis. The urine was scanty and albuminous, with or without the presence of casts. The kidneys post-mortem showed little that was abnormal to the naked eye, but microscopically interstitial cellular infiltration, formation of new connective tissue, with a varying degree of catarrhal exudation in the tubules. Syphilitic infants might succumb to this within the first few weeks or months of birth. Chronic interstitial nephritis appeared to be the result of the acute form. Clinically and pathologically it was indistinguishable from the chronic interstitial nephritis of adults. Whether the two forms were essentially syphilitic was a matter for discussion. It was certain that in a small proportion of cases congenital syphilis had been recorded, but, on the other hand, no personal or parental history of syphilis was forthcoming in the majority of both acute and chronic cases of interstitial nephritis in infancy and childhood. Dr. Guthrie concluded that a certain proportion of cases might be due to congenital syphilis, whilst others were of septic origin.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, December 5th, 1907.

The President, Mr. **Frank T. Paul**, F.R.C.S., in the Chair.

Amongst a large number of clinical cases shown were the following:—

Dr. T. R. **Bradshaw** showed three patients, adults, suffering from acute anterior poliomyelitis. (1) A man, æt. 53. Sudden onset, hands giving way while patient was sitting on a gate. The paralysis was at first attributed to the fall. Characteristic paralysis, with wasting affecting forearms and thighs. (2) A man, æt. 28. Ill two days with what was supposed to be influenza, and then found to have paralysis of one arm. Condition characteristic. These two cases occurred within a week of one another, and the patients lived in the same district, suggesting an infective source for the disease. (3) Woman, æt. 35. Two years ago sudden paralysis of right leg, slightly of left. At present foot-drop, with coldness and blueness of feet.

Dr. R. J. M. **Buchanan** showed a child who had suffered from tubercular meningitis, and recovered. After an illness of four weeks, and coma for eight days, lumbar puncture was performed, and 20 c.c. of cerebro-spinal fluid removed, containing lymphocytes, but no meningococci were found. The symptoms were classical. An inoculation of 1-4,000 mg. new tuberculin was given. The child showed immediate signs of improvement, and gradually recovered consciousness. Three weeks later the above treatm was repeated, after which the child made an uninterrupted recovery, is now quite intelligent and able to run about. Calmette's tuberculin reaction on the conjunctiva was positive.

Dr. **Buchanan** also showed photographs, and described a case of chloroma in a child of 4½ years. The symptoms commenced with anæmia in July, right facial paralysis with pain in the right ear in October, and exophthalmos followed. The orbital growth is proceeding rapidly. Characteristic blood changes are present, the leucocytosis increasing from 25,000 to 250,000 per c.mm. in a few days.

Dr. J. **Lloyd Roberts** showed:—(1) A case of chancre of the scalp, caused by the patient butting his head in a scuffle against the teeth of a man who had secondary symptoms of syphilis. (2) A case of lead paralysis, which improved rapidly under treatment with iodipin, after potassium iodide had been tried for some time without apparent benefit. (3) A case of transverse myelitis, which improved to a certain extent under potassium iodide and mercury, and was now making more rapid progress with iodipin.

Dr. **Percy Marsh** showed:—(1) A boy, æt. 1 year 9 months, who was admitted into the children's infirmary on November 5th with a history of having had meningitis, with retraction of the head, seven weeks previously. On admission he had marked "intention tremors" of all the parts of the body. The cerebro-spinal fluid was turbid, reduced Fehling, and showed a large number of polymorpho-nuclear leucocytes; a growth of staphylococcus aureus was obtained. There was no optic neuritis, nor atrophy of the disc. (2) A girl, æt. 8, with insular sclerosis. Symptoms were first noticed four years ago after a fall on the head. She now had typical intention tremor, with nystagmus and scanning speech. There was no optic atrophy, and the cerebro-spinal fluid was normal. (3) Two cases of lymphadenoma—(*a*) the ordinary type, with a lymphocytosis varying from 48 to 60 per cent., with a normal blood count; (*b*) sub-lymphatic type. Calmette's ophthalmo-reaction negative. Marked improvement under full doses of arsenic and X-rays.

Mr. R. C. **Dun**:—(1) General thyroid enlargement in a girl 12 years old; tremors and rapid heart's action, but no exophthalmos. (2) Lymphadenoma. (3) Meningocele and accessory auricles. (4) Congenital deformity of hand (two cases), showing syndactylism, microdactylism, and congenital lateral deviation of the fingers. (5) Congenital deformity of lower extremities (two cases). (6) Ischæmic contraction of muscles of forearm following fracture of the humerus.

Dr. H. **Leslie Roberts** showed the following:—(1) Rodent ulcer of nose of two years duration cured by X-rays. (2) Lupoid gummata covering the whole of the front of the neck and a portion of the nose and upper lip. The resemblance to lupus was extraordinary, but the disease was of only one year's duration. (3) Tubercules in a woman, æt. 47, involving the right upper eyelid, the cheek and upper lip, of 3½ years' duration. A sister died of consumption, and the patient had had more than one "hæmorrhage." The lesions were multiple, discrete uniform in their objective characters and their mode of evolution. Each lesion presented the appearance of a slightly elevated convex spot of bluish red colour. At the centre of each spot a slight amount of fluid exudate preceded quiet necrosis, the loss of tissue being followed by a minute depressed scar. (4) Acquired syphilis in a girl, æt. 12. The intoxication rash covered most of the body. The chancre was on the lip, and resembled impetigo. (5) Multiple lupus in a boy, and complicated by secondary inoculations.

Dr. **Stopford Taylor** and Dr. **Mackenna** showed the following cases of skin disease:—(1) Enchondroma cutis in a female child, æt. 15 months. She is the fifth child in a family, all of whom are healthy. In the skin on the outer side of the left thigh, the front of the chest, the back, the left side of the scalp, and the left forearm just above the wrist, are plates of cartilage varying in size from 1¾ in. to the size of a split pea. Over these deposits the skin has a peculiar violaceous hue, and shows here and there a pearly deposit. The cartilaginous nature of the plaques has been confirmed microscopically, and at points the cartilage which is lying in the true skin shows signs of ossification. So far as is known, this is the first case of the kind that has been shown in England. (2) Psorospermosis follicularis vegetans (Darier's disease) in a young woman æt. 32. The disease affects chiefly the neck, the upper part of the chest and back, and the arms. It had lasted for seven years. (3) Ichthyosis nigricans—a very severe case in a boy of 11. (4) Cases of lupus showing Calmette's ophthalmo-reaction. (5) Follicles of the fingers and hands of 13 years' duration in a young woman. The tubercular nature of the disease was confirmed by the presence of tubercular glands in the neck. (6) Case of severe papular syphilis. (7) A Case of hypertrophic lupus of six months' duration (8) A series of 40 wax casts taken from patients suffering from different forms of skin disease.

Mr. J. **Bark** showed cases of the complete mastoid operation, and Heath's conservative method. The patients had been the subjects of fœtid middle ear suppuration of from 3 to 12 years' duration. The results were excellent, and the hearing after Heath's operation was most marked.

Cases were also shown by Dr. N. Raw, Mr. C. T. Holland, Dr. F. H. Barendt, Dr. K. Grossman, Mr. R. J. Hamilton, Mr. A. M. Walker, Mr. T. Guthrie, Dr. McDougall, and Mr. K. W. Monsarrat; an operating table by Dr. Blair Bell; radiographs by Dr. D. Morgan.

WEST LONDON MEDICO - CHIRURGICAL SOCIETY.

Meeting held December 6th, 1907.

The President, Mr. **Richard Lake**, F.R.C.S., in the Chair.

Dr. **Mansell Moullin** read a paper on the

TREATMENT OF UTERINE FIBROIDS,

advocating early operation in all cases giving rise to symptoms. The troubles arising from these tumours were, he remarked, so grave and so varied that, considering the brilliant results now attained by surgery, it seemed worse than folly to allow a woman to spend years of her life as a chronic invalid, exposed to all these risks, when the remedy was at hand—a remedy which might, and often did, become a matter of necessity at a later date. He described the technique of hysterectomy, and advocated the supra-vaginal operation in the very great majority of cases. He had lost but one case in 78 operations. The danger of the operation had been reduced to a minimum, and need not deter one urging radical treatment when called for.

Mr. **Sampson Handley** read a paper on

CHRONIC APPENDICITIS IN WOMEN.

The study of chronic appendicitis had been retarded by two causes—firstly, by the erroneous belief that an appendix free from adhesions is necessarily a healthy appendix; secondly, by the divorce which in England exists between the practice of general surgery and that of gynæcology. The most striking symptoms of chronic appendicitis were located in the female pelvic organs. Of these the most constant and important was dysmenorrhœa. The history of a painful menstrual period precipitated (or brought back after its cessation) by what appeared to be an attack of acute indigestion, was very characteristic of chronic appendicitis. But the main object of his paper was to show that chronic appendicitis in women is frequently accompanied by a definite physical sign. This sign was an enlargement of the right ovary up to double its normal size owing to the congestion and lymphatic stasis produced by the near neighbourhood of an inflammatory focus in the appendix. In such cases the diagnosis of chronic ovaritis was usually made, and futile gynæcological treatment was often carried out for long periods. In one of his own cases appendectomy cured a patient who had submitted without benefit to douching, blisters, tampons, and local applications to the cervical canal, over a period of five years. The appendix was free from adhesions, and its lumen contained a small collection of pus.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

Meeting held December 11th, 1907,
at Hanover Square, London.

The President, Dr. W. J. Tyson (Folkestone), in the Chair.

Dr. Edgecombe (Harrogate) read a paper on

BLOOD PRESSURE IN SPA PRACTICE,

the purpose of which was to show the utility of making observations of blood pressure as an aid to diagnosis, and as a guide to hydro-therapeutic treatment. After pointing out that most cases going to spas suffer from chronic diseases of nutrition, in which blood pressure changes afford some indication of the state of tissues nutrition, he discussed the following conditions in relation to blood pressure: arterio-sclerosis, hyperpyesis, gout, fibrositis, heart disease, anæmia, and the menopause, giving cases in illustration of his views. He concluded with a plea for the routine examination of blood pressure in spa practice as affording more precise information than could be obtained by the digital method.

Dr. Leonard Williams, in support of Dr. Edgecombe's views, strongly deprecated the pretensions of those who claimed to be able to estimate the degree of blood pressure by digital examination alone. He recalled Professor Clifford Allbutt's dictum to the effect that it was as absurd to discuss blood pressure in the absence of an instrument as it was futile to discuss temperature in the absence of a thermometer. In further support of Dr. Edgecombe's views he insisted upon the existence of high blood pressure as a functional manifestation which was altogether independent of granular kidney or other structural disease except in so far as its continuance tended to produce these conditions. He discussed the spa and climatic treatment, and concluded that such benefits as were peculiar to this form of treatment resided rather in the greater readiness of patients to obey orders at health resorts than in any properties inherent in the waters, more especially at British spas.

Dr. George Oliver (Harrogate) discussed the blood pressure in gout and the menopause, and gave an outline of his recent observations on the diagnostic value of the armlet method in arterio-sclerosis. He demonstrated his improved hæmomanometer, provided with a supplementary method, which serves as a check against arterio-sclerosis.

Dr. Harry Campbell contended that it was possible to estimate the radial blood-pressure by the finger. He referred to the function of the muscular media in preventing vascular stretching.

The discussion was adjourned to January 29th, 1908.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Dec. 13th 1907.

At the Verein für Innere Medizin, Hr. Bleichrœder showed a six to seven months' fœtus that had been sent to him for examination. The autopsy showed a diaphragmatic hernia, with sac complete, on the left side, the sac containing all the abdominal viscera. Herniæ of the diaphragm were mostly on the left side in a proportion of 6 to 1. It was a disease of development due to patency of the ductus communis. Below the diaphragm was a horse-shoe kidney with three ureters, one of which was in a state of hydronephrosis.

Hr. Benno Levy remarked that he had shown a similar case some years ago, in which, however, there was almost complete absence of the diaphragm, and the child had been carried to full term. It was not clear to him why the child shown had died so early. The hernia of the diaphragm could scarcely have been the cause of death.

Hr. Klebs showed a guinea-pig that had been infected with

HUMAN TUBERCULOUS SPUTUM

120 days before, and became affected with widespread tuberculosis. He had now brought about its recovery by injections with his own serum. During this process of recovery the tubercle bacilli had been led to the glands, and enormous swelling of the bronchial glands was seen in the preparations. The animal through accident had died.

Hr. Erich Schlesinger spoke on

THE TREATMENT OF NEURALGIAS BY INJECTION.

He recommended the use of isotonic + 0° solutions of salt. Formerly strong narcotic solutions were made use of; then it was found that weak solutions did as well, and now we thought we saw that the chief thing was the mechanical action of the injection, and that the simple isotonic saline solution was sufficient, so long as a larger quantity was injected than formerly. The speaker had obtained brilliant results, especially in the treatment of sciatica, that obstinate complaint. The injection should not be passed into the nerve itself, but into the adjacent tissues.

Hr. Peritz was of opinion that occasional successes had been obtained with all kinds of injection material. It was known that a saline solution was generally sufficient. Alcohol injections were specially recommended for old trigeminus neuralgias. The speaker had laid stress on his success in chronic sciaticas. All cases of so-called chronic sciaticas were myalgias, and not sciatica. How long had he observed his cases? That a saline solution of 0° was given was scarcely possible.

Hr. Remak observed that sciatica cases ran very different courses. Some yielded to any treatment, some to none at all. Salt water injections were harmless, at any rate. That could not be said of other injections, as paralyses were not unfrequently seen to follow injections of alcohol in consequence of parenchymatous neuritis, and just as much as from the injections of ether formerly employed. One could not always avoid injection into the nerve; it got there sometimes without intending it.

Hr. Kraus said that chronic sciatica was known to be the crux medicorum. Whatever treatment was used, complete recovery was rare. It was a great advantage when a method of treatment made patients fit for work. Regarding injections of saline solutions, he could express himself rather more favourably than Peritz. Chronic sciaticas were favourably influenced by it. They had tried everything in his klinik. From his own experience he should recommend blister plasters.

Hr. Rothmann, jun., thought success was obtained by suggestion, and not by injection.

Hr. Alexander said that good results were obtained by saline injections before now. Chronic sciaticas, however, had their seat in the muscles, as the result of acute sciatica. In the latter the muscles were kept in a certain position in which the pain was least felt. This fixed position, by constant tension of the muscles, led to myositis. We therefore found points that were painful on pressure in chronic sciatica that had nothing to do with the nerve trunks, but the terminals of the nerves which were compressed by the muscles. By the injection of larger quantities of fluid the terminals were relieved from pressure, and the cause of the pain removed.

At the Ophthalmological Society, Hr. Adam showed a female with pulsating exopthalmos. Nine years before she had been operated on for an orbital tumour that was either a sarcoma or an enchondroma, and for a year and a half there had been exophthalmos that could be pressed back with some force. There was no arterio-venous aneurysm; it could not be a solid tumour; it could be only a vascular tumour. To determine whether it was arterial or venous, the patient was examined with the head hanging down, and forced to one side, whilst the jugular was compressed. No increase of the exophthalmos took place, so the cause was probably not penous. Considering that it took not a little force to press the eyeball back, it was one with a very free vascular supply, most probably an angio-sarcoma.

AUSTRIA.

Vienna, Dec. 22nd, 1907.

Ischialgia and Infiltration.

At the Gesellschaft, Bum presented six patients whom he had treated with salt injections for chronic ischialgia. All of them had suffered for more than two years with an excruciating pain in the ischial nerve. Bum injected an "isotonic" solution of table salt, under high pressure, with a canula, into the upper part of the thigh. Bum does not insert the canula, as Grossmann, Lange, Kellermann do, into the gluteal muscle, but prefers inserting at the junction of the long head of the biceps femoris and the gluteus maximus, where no wounding of muscles or large vessels can take place. This injection or infiltration of the nerve distends the sheath into a spindle shape, acting mechanically on the neurilemma, and subsequently producing adhesion of the sheath with its surroundings. The action is therefore at first an intense distension, followed by an active contraction of the nerve.

The six patients presented had been free from pain for seven to fourteen months since the operation, although all of them had suffered from pain and been disabled for work for two years preceding the operation, but are now quite fit for duty. He had now similarly operated upon 81 cases, with 63 per cent. perfectly cured, and 21 per cent. greatly relieved. This infiltration treatment is contra-indicated where the cause is neuritis at the root of the nerve, advanced arterio-sclerosis and hysteria. It need not be added that the infiltrating fluid should be perfectly aseptic.

Noorden was quite convinced that Bum's method was the most preferable and free from the dangers that the other methods were subject to, and Laudler was of the same opinion.

Embolism of Pulmonary Artery.

Stoerk exhibited preparations of embolism of the pulmonary artery and branches that had occurred eight days after an operation for umbilical hernia. The ascending aorta and arch were perfectly closed, while the foramen ovale was open. The arteries of the right kidney and the finer branches to the spleen were also closed by emboli. Eiselsberg, who performed the operation, said that the patient was perfectly well on the following day after the hernia was replaced, and no complication threatened. Suddenly, however, on the third day progressive paralysis commenced. Trendelenburg's method of dealing with such cases was immediately discussed, which is that after four or eight hours, when death threatens, the right heart should be opened and the embolus aspirated from the pulmonary artery. Eiselsberg could not decide on this heroic treatment, and the patient died. After examining the heart, it was concluded that the operation would have been of no avail owing to the open foramen ovale.

Bier's Suction Treatment.

Jerusalem pointed out a new indication for Bier's suction treatment in the after-effects of appendicitis. From the beginning he applies Bier's instrument with curved edges for 20 to 30 minutes over the right side of the abdomen. After this is done it is less sensitive and resistant, while the cicatrix becomes soft and the pain much less. The applications vary between 6 and 20. He also finds that Bier's treatment has a beneficial effect on alleviating pain in the abdomen and hastening absorption in perityphlitis, particularly where the infiltration is subcutaneous. He also finds it of much advantage in healing fistulæ, and after laparotomy.

Lead Poisoning.

Teleky briefly related the history of several lead poisoning cases in shoemakers, where the extensor muscles were affected by rubbing a white cream into the leather. Another case was a locksmith with severe encephalopathia saturnia, with extensors also paralysed, the latter being due to the use of a paste. Another was a hatter with thickening of the inner surface of the fingers and thumbs, due to the colophonium or dark resin used in the trade.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Late Professor Annandale.—The news of Professor Annandale's tragically sudden death on December 20th was received in Edinburgh with the most profound regret. It is hard to believe that, without any warning, so well-known a figure has been snatched from our midst. Professor Annandale was apparently in his ordinary health on the day before his death. He had performed his ordinary day's work at the Infirmary, and dined at home as usual. The next morning he was found dead in his bed by the servant who went to arouse him. So little was Professor Annandale deemed to be ailing, much less seriously ill, that he was looking forward to being present on the 21st at the prize presentation of the Royal Garrison Artillery, of which regiment his son-in-law, Mr. Norman Mitchell James, is one of the officers. Professor Annandale was a native of Newcastle, but spent the greatest part of his life in Edinburgh. He assisted Professor Lyme, and in 1877 was appointed Regius Professor of Clinical Surgery, and had thus been for thirty years a conspicuous figure in the University and social life of the city. His death was totally unexpected, and the deepest sympathy is felt for his family in their great and unlooked-for bereavement.

The Treatment of Incipient Mental Disease in the Edinburgh Infirmary.—Dr. Clouston has written to the *Scotsman* a second letter advocating this scheme, and giving the results of a postcard plebiscite among the practitioners of Edinburgh. He sent to each of the 379 medical men resident in Edinburgh and Leith the query, "Are you in favour of the establishment of psychiatric wards in the Royal Infirmary for the treatment of early, suitable and transient forms of mental disease?" Two hundred and fifty-eight replies were received; 212, or 82 per cent., answered "Yes"; 26, or 10 per cent., answered "No"; while conditional answers, merely approving the principle, were received from 20. There is thus a very large degree of unanimity in the minds of the profession in favour of Dr. Clouston's proposals. The chief objections put forward are that there are more urgent matters awaiting solution by the managers; that the institution has not the funds to carry out the scheme; that such patients might be a source of danger and annoyance to the other patients; that there is no room within the present Infirmary grounds for such wards; and that there would be legal difficulties and risks. Dr. Clouston's general answer to most of these is, that such wards are successful elsewhere.

Falkirk Fever Hospital.—The Local Government Board inquiry into the charges of maladministration was opened at Falkirk on December 16th. The charges of mismanagement were made by the Rev. N. W. Miskimmin in the course of his campaign in the recent municipal election. The complaints came under four categories:—(1) Irregularities having occurred at the hospital; (2) charge of professional negligence; (3) charge of neglect; (4) a charge of extravagance. Mr. Black, on behalf of the complainers, asked that the inquiry be adjourned in order that they might have adequate time to prepare their case. The object of the inquiry was to restore public confidence, and unless it was thorough and effective that would not be achieved. He suggested that they might lodge a written statement of their case, and the Town Council be asked to answer their charges. Mr Allan, for the Town Council, concurred in the request. Statements had been made against the hospital, and the people had been appealed to not to allow their children or relatives to be taken there. Sheriff Fleming and Sir Henry Littlejohn, who have been appointed to investigate the case, decided, however, to take Mr Miskimmin's evidence before adjourning. The rev. gentleman stated that he had heard complaints, and that these had been substantiated by other persons. The convener of the Public Health Committee used conveyances belonging to the hospital very much longer than was reasonable. There was extravagance in the provision of liquor and foodstuffs, and laxity in ordinary goods. A child of eight had been ill-treated in hospital. According to one order, 72 lbs. of tobacco had been procured, and all this had not been consumed in the hospital, but some had been carried away. Reflections were also made on the quarantine methods during the recent smallpox epidemic, and on the internal administration—card-playing, concerts, organ-playing, late at night. He wanted to see changes both in the convenership of the Public Health Committee and in the Medical Officership. The inquiry was adjourned until January 15th.

The Medical and Dental Defence Union of Scotland.—The fifth annual report records substantial progress in the affairs of the Union. The membership, now 966, has increased by 112 new names during the year. The financial position of the Union is satisfactory. After writing off the last instalment of the preliminary expenses, a balance of £271 has been transferred from the revenue account to the balance-sheet, so that the Union now has £929 9s. to its credit. The Union has done a great deal of useful work in advising and assisting its members, adjusting disputes, obtaining apologies, etc. The annual subscription is only 10s.—a mere trifle, considering the advantages of belonging to the Defence Union.

LETTERS TO THE EDITOR.

THE BRITISH MEDICAL ASSOCIATION.

To the Editor of The Medical Press and Circular.

Sir,—Your editorial references to the British Medical Association are invariably couched in terms of kindness and sympathy, and your note this week forms no exception to the rule. Full of goodwill as we may be to the Association, and alive as we may be to the uselessness, and often the unfairness of mere fault-finding, it is unnecessary to disguise the fact that widespread discontent with the management of the Association exists among large sections of the members. This discontent helps to explain the fact that the membership of the Association numbers less than 20,000 all told—that is about half the numbers eligible in these islands, and within the British Empire. The Association boasts of an enormous income, but of this the greater part is absorbed in the production of the journal, and there are only meagre funds left for activity in other directions. The matter was well put by a correspondent in your pages some time ago. He said the B.M.A. is in reality at present solely a co-operative society for the publication of a journal enormously costly to produce, but certainly supplied to the members at a cheap rate. The journal is too big. In every direction, and, particularly in the editorial department, it could be reduced, and with advantage, to about one quarter of its present bulk. The scientific contributions could also be compressed easily, and to the benefit of the readers, to almost the same extent. The circulation would still command the advertisers, whilst a few thousands a year would be saved for objects now untouched for lack of money. The Association is doing some small thing towards the promotion of scientific research; but if it were able to speak in the name of the majority of the profession, and possessed the organisation necessary to make that voice heard, it might do much more, not only towards the advancement of science, but towards those reforms of so much more vital importance to the bulk of the profession which you, Sir, are so well doing your part to promote.

I am, Sir, yours truly,
Member B.M.A.
December 20th, 1907.

QUACKERY OF QUACKS.

To the Editor of The Medical Press and Circular.

Sir,—I am pleased you have opened your columns for a discussion of the all-absorbing and important question of quackery. I think we might look at our own profession and see if any quackery exists among ourselves. Let me make a few suggestions for your many readers to explore and report their experiences upon. Commencing at the top of the tree, consultants, so-called, in many cases, really self-glorified G.P.'s, Let me ask your readers to record their experiences. Then among the G.P.'s. let me cite one case, and I could cite more. Dr. A. was treating a lady with cardiac dropsy with digitalis. The lady being dissatisfied with her progress called in Dr. B., who remarked to her, no wonder you are not progressing. Dr. A. is treating you quite wrongly. The patient died about a month afterwards, and the family then employed Dr. B. I regard Dr. B. as a quack of the worst order.

Let me glance at the nursing profession. I attended a lady in her confinement, and who employed a trained nurse to nurse her. I ordered an aperient. The nurse remarked *I* always order salts for my patients, you see they act upon the liver. I dealt with this nurse very promptly and effectually. I ask, if a nurse will address a doctor like this, what will her conversation be like, in the absence of the doctor? I shudder to think of it?

I think that many of your readers can give their personal experience upon the subject of midwives. Quackery of the rankest description thrives here. Then we have massage nurses. A patient was suffering from peripheral neuritis, and a nurse was employed to massage the lower extremities. The patient asked me, what is the potential of muscle? The nurse had remarked to her that the potential of her calf muscles was low. I replied, the potential of a muscle is a meaningless term employed by the ignorant to cover their ignorance.

Quackery such as I have mentioned means when referring to the consultant's and G.P.'s. that we have failed to act as gentlemen. When we come to the nursing profession and midwives we must ask ourselves the question, Who is to blame? Surely, ourselves. We have the teaching and examining of them; and we do not sufficiently impress upon them that the superficial knowledge of anatomy, physiology, etc., which they learn, is merely to enable them to take an intelligent interest in their nursing work, and that their duty when nursing a case is faithfully to carry out the instruction of the medical man who is attending, and is alone responsible for the case.

I leave your readers to amplify these remarks. I am sure much practical advantage would accrue from such a discussion.

I am, Sir, your truly,
Bedford, Dec., 18th, 1907. S. J. Ross.

THE BROWN DOG INCIDENT.

To the Editor of The Medical Press and Circular.

Sir,—I had not intended, as I said, to trouble you further, but you have apparently entirely missed my points as to your extraordinary assertion that "animal experimentation had provided the children of Battersea with the only means" of coping efficiently with an attack of diphtheria.

At this moment I am not concerned to either endorse or deny an assertion that diphtheric serum is a very efficient remedy. That is not the point. I again repeat that your assertion is in direct contradiction of established facts on the *ipse dixits* of authorities at least as high as the Editor of The Medical Press, which is no doubt very great. I have read all your articles, and, fortunately, a very great deal besides, or I might take a more narrow and prejudiced view, and fall into the making of so untenable an assertion as the one I have challenged.

I am, Sir, yours truly,
George W. F. Robbins,
Battersea, London, S.W., Secretary.
December 20th, 1907.

[This letter surely requires no comment. We have given Mr. Robbins plenty of room in our columns, and if this letter represents the best he can do, we think it may appropriately wind up the discussion.—Ed. M. P. and C.]

OBITUARY.

REGIUS PROFESSOR OF SURGERY THOMAS ANNANDALE.

The close of the year has been sadly marked and mourned by the profession in Edinburgh, owing to the sudden death of two of its greatest surgeons, the death of Regius Professor Thomas Annandale occurring on Friday last, and that of Sir Patrick Heron Watson on Saturday. Professor Annandale was Surgeon to H.M. the King's Bodyguard for Scotland, Surgeon to the Royal Infirmary, and Consulting Surgeon to the Royal Hospital for Sick Children, Edinburgh. Time precludes us giving more than this brief announcement of the sudden death of these distinguished surgeons. We hope to present a fuller account of their careers in our next.

SIR PATRICK HERON WATSON, M.D., F.R.S., etc.

We regret to announce the sudden death, from heart failure, of Sir Patrick Heron Watson, who died at his residence in Charlotte Square, Edinburgh, on Saturday last.

Sir Patrick, who was born in 1832, was Surgeon-in-Ordinary to the late Queen Victoria, and Surgeon-in-Ordinary to the King in Scotland. He was a past President of the Royal College of Surgeons of Edinburgh, and at the time of his death held the post of Consulting Surgeon to the Royal Infirmary and to Chalmers' Hospital, Edinburgh, receiving the honour of Knighthood in 1903.

JOSEPH LLEWELYN WILLIAMS, M.B., C.M.Ed,, M.R.C.S., J.P.

We regret to record the death, on December 13th, of Dr. J. Ll. Williams, J.P., of Wrexham. He was 63 years of age, and was married to a daughter of the late Mr. Edward Evans. Dr. Williams graduated at Edinburgh, and, after being at St. Bartholomew's Hospital, London, and having obtained the degrees of M.B., C.M., and M.R.C.S., London, he was appointed house surgeon at the Liverpool Northern Hospital. Subsequently he became first Medical Officer of Health for Wrexham, and last year he was appointed Medical Referee under the new Compensation Act. About three weeks ago Dr. Williams was seized with heart trouble, and death was due to cardiac failure. Dr. Williams had an extensive practice in the Wrexham district, and for the past six years had been in partnership with Dr. S. Edwards Jones.

REVIEWS OF BOOKS.

THE PREVENTION OF INFECTIOUS DISEASES (a).

The title of Dr. McVail's last book, "The Prevention of Infectious Diseases," led us rather to expect a work on the subject which broke new and interesting ground, for it cannot be said that much is generally known about the prevention of infectious diseases, at any rate as regards the common infectious diseases of this country. But we find very little in it beyond the usual hardy perennials—isolation, disinfection, vaccination, and so on—and these are merely described as we are accustomed to seeing them described. The reason of the somewhat platitudinous character of the book is that it is a reprint of the Lane Lectures which Dr. McVail gave last year at the Cooper Medical College at San Francisco, and presumably the facts which sound in our ears like a thrice-told tale were to the Pacific audience both novel and interesting. True it is that Dr. McVail has embellished the ordinary run of the narrative with incidents drawn from his own experience, and that here and there we get extracts from reports and registers which do not usually come our way; but, after all said and done, the book is more likely to be of service to the student working for the D.P.H. and to the intelligent layman than to the medical officer of health hungering for fresh tips and pastures new. For instance, in a book of this kind, dealing solely with the prevention of infectious diseases, we should have expected a full and satisfactory statement of the arguments for and against hospital isolation in scarlet fever; but the author, after a few general remarks, dismisses the subject by saying, "I am not going to attempt to argue out this question of hospital influence in scarlet fever." Then, too, with regard to return cases, we hoped to find a full discussion of that lively and disquieting problem, but it receives a bare half-page, and even in that no figures are set out. Now we should have thought questions of this kind deserving of space which is actually occupied with such matter as descriptions of the diphtheria plague, and tubercle bacilli, which are to be found in every text-book; but this brings us back to the point that the work before us is really an elementary one, and that it was brought out for a special purpose and written *ad hoc*. The views are all of an orthodox character, and pleasantly conveyed.

FUNCTIONAL NERVOUS DISORDERS IN CHILDHOOD (a).

Dr. Leonard Guthrie, in the preface to his "Functional Nervous Disorders in Childhood," anticipates that there may be critics and reviewers so churlish as to say, with Merlin—

> "None can read the text, not even I."

Let us hasten to assure him that there is one reviewer at least who not only has read the text but whose pleasure it will be to place it in that select corner of his bookcase over which is written (metaphorically), *Non legendi sed lectitandi*. For this is no ordinary book of scissors, paste, and midnight oil, embellished with extracts from the case-book, and triumphant vindications of the author's theories by reference to success in individual instances which no one else has the opportunity of verifying. It is, on the contrary, an unusually original treatise, dealing with a dark corner in medicine which it illumines with the skill of a sagacious physician, the elegance of a fastidious scholar, and the wit of a consummate man of the world. We do not know whether to praise more the sound learning it reveals, or the brilliance of the style in which it is written; both are admirable. One conclusion that is irresistibly borne in on us is that Dr. Guthrie himself must have been a neurotic child, for not otherwise could he have experienced those poignant sensations which he describes with such fidelity in the first ten chapters, and only personal suffering could have helped him so justly to trounce the unthinking cruelty of pastors and masters towards highly-strung, emotional and shy children. We strongly suspect that some of the excellent stories of childhood's woes, and even shortcomings, are put impersonally on the same principle that the fourth evangelist writes of "the other disciple." But this intense dramatic sympathy with objects of his solicitude does not carry the author into mild and indulgent advice to parents and medical men; on the contrary, nothing could be more measured or more sane than his views of child management generally, and nothing distinguishes him so much as his aversion to faddism and ecstaticism. If the overdoing of good causes could be killed by satire, the thick-and-thin advocates of intemperate "temperance teaching," the total abolitionists of juvenile smoking, the excusers of vice on the "uric acid" hypothesis, and similar excellent and ardent people, would find their activities vastly curtailed. We would that this book might fall into the hands of many of our nascent school hygienists, for they would be bound to recognise that, whilst the author is a master of his subject and an intimate friend of children, he is no partisan of wild experiments of the doctrinaire type which so many enthusiasts are so keen on instituting. Throughout the book, both in the first ten chapters and in the last eleven more strictly clinical ones, Dr. Guthrie shows in a dozen ways his faculty for original observation. In the chapter on "The Fears of Neurotic Children," Dr. Guthrie speaks about gloomy religious teaching:—"Although we may entertain doubts ourselves as to the immortality of moles and pet canaries, there is no occasion to allow our reservations to distress our children." And again:—"The same remark applies to the teaching of all moral, social, and political questions. Exaggerated statements and extreme and biassed views on any topics such as the evils of drink, tea, and tobacco, the land and poor law questions, are in the highest degree injurious to neurotic children." The assertion that smoking in children stunts growth meets with criticism. "It is doubtful whether the most inveterate non-smoker can add an inch, much less a cubit, to his stature," and the sexual purist who has a keen nose for "pollution" is told that "a child who suffers from habit spasm, or happens to be dreamy, shy, and miserable, is not necessarily addicted to secret sins." It is, however, hardly fair to give extracts apart from the "atmosphere" of the book, and that atmosphere we can commend as having tonic qualities seldom found in the literary climatology of medicine.

(a) "Functional Nervous Disorders in Childhood." By Leonard G. Guthrie, M.A., M.D., F.R.C.P., Senior Physician to Paddington Green Children's Hospital. London: Henry Frowde, Oxford University Press. Hodder and Stoughton. 1907.

DIAGNOSIS OF ORGANIC NERVOUS DISEASES. (*a*).

Since the first edition of this well-known book 15 years ago the progress of neurology has, of course, been very great, and Dr. Clark had a heavy task in attempting to bring the book up-to-date. He has performed this in an excellent manner without altering the original form of the book, or disturbing the order of subjects that was so characteristic and practical a feature in the first edition. The eight chapters deal respectively with: The Structure and Functions of the Nervous System, the Symptomatology of Nervous Disorders, the Diagnosis of the Position of the Lesion, the Diagnosis of the Nature of the Lesion, the Diagnosis of Clinical Types, the Distinction of Functional and Organic Disease, the Examination of the Patient, Illustrations of Diagnosis. On the whole the revision is most creditable, and an account is given of the most recent advances, including a short description of lumbar puncture. There are certain exceptions to this, however; for instance, the section on cerebellar localisation is poor, and at least twice as much practical and precise knowledge could have been put in the same space. While, as said, these lapses are exceptional in the main section of the book, the same cannot be said of the chapter (pp. 556-601) on Functional Diseases, which is extremely poor and shows an ignorance of all modern work on the subject. When the first sentence on hysteria contains the statement that the affection consists in a primary derangement of the highest cerebral centres—a statement entirely unfounded on any evidence whatever, and contradicted by all our present knowledge of the subject—we are not surprised to find later on the hackneyed errors dating 30 years back, such as that the face is never involved in hysterial hemiplegia, that there is never ankle clonus on the paralysed side unless there is great contracture, that the onset of the hemiplegia is never accompanied by loss of consciousness, etc.

With the omission of this chapter, however, the book is exceedingly good, and to be warmly recommended as one of the most useful and valuable books on this difficult speciality that we possess at the present day.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Tumour of the Breast.—Mr. James Berry operated on a middle-aged woman, æt. 47, who had noticed for a few weeks a small lump in her left breast. This was as large as a hazel nut, smooth, firm, and evidently in the breast tissue, although quite close to the skin. The latter, however, was in no way adherent to the lump, nor did the nipple show any signs of retraction. No definite enlargement or infiltration of the axillary glands could be felt. With the exception of some heart disease, the patient's health was otherwise good. Mr. Berry pointed out that the diagnosis in such a case lay between an involution cyst and a malignant tumour. The short history, the smoothness and close proximity of the tumour to the skin without involving the latter were all in favour of a cyst. On the other hand, the mere fact that a hard lump existed in the breast of a middle-aged woman was sufficient to raise a strong suspicion of malignancy in the absence of definite signs to the contrary. If there were the least doubt, the proper course to pursue, he said, was to remove such a tumour locally, and then if it proved to be malignant to at once proceed with the larger operation of removal of the whole breast, pectoral muscle, and axillary glands. He thought it better to excise the piece of breast containing the tumour before cutting into the latter, as a better view of the surface of the growth could thereby be obtained. He considered it excessively rare for a surgeon of any experience not to be able to tell at once by naked eye examination of the cut section whether he had to deal with a malignant or an innocent tumour. Occasionally, but very rarely, it happened that under such conditions uncertainty still prevailed, and it might be necessary to have a microscopical section cut on the spot before a definite diagnosis could be made. He strongly deprecated the practice of cutting into a doubtful tumour, and then, if it proved to be malignant, postponing for a few days the performance of the larger operation of removal of the whole breast, etc. Such a proceeding favoured general dissemination, and distinctly lessened the prospect of ultimate cure. The tumour, together with a small portion of the breast, was thereupon removed, and it was found to be a firm, non-encapsuled, solid growth, of the colour and consistency of a raw potato—in other words, a typical scirrhous carcinoma. The larger operation of complete removal of the whole breast, together with the pectoral muscle and axillary glands, was then carried out, special care being taken to remove plenty of the skin because of the close proximity of the tumour to it. It was noticeable that the axillary glands, although not appreciably affected clinically, nevertheless were found to be distinctly affected when the axilla was opened, and some of them on section presented distinct traces of carcinomatous deposit. Mr. Berry said that the great points in regard to naked eye diagnosis of the tumour were: its non-encapsulation and its firmness. Chronic inflammatory lumps in the breast might contain a good deal of fibrous tissue, but they were usually somewhat elastic, and lacked the firm, dense consistency of carcinoma. As the patient had fortunately been operated upon in an early stage of the disease, and the removal had been a very complete one, he thought the prognosis might reasonably be considered a good one. He, like most other surgeons, had many patients on whom he had performed similar operations several years ago, and who had remained quite free from the disease. He also drew attention to the insertion of a large drainage tube at the lower and back part of the axilla. He considered it much safer in cases of cancer to allow the serum and other secretions of the wound to drain away in the first few hours after the operation, rather than to leave them to be absorbed from the wound. The drainage tube should be removed at the latest on the day after the operation.

The patient made a normal recovery, and will be sent back to her doctor in the country in a week after the operation.

"Diagnosis of Organic Nervous Diseases." By Christian Herter, M.D. Revised and enlarged by Pierce Clarke, M.D. Pp. 690. New York and London: Putnam's Sons. 1907. Price 12s. 6d. net.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Calmette's Ophthalmo-Reaction to Tuberculin.—Boyd (*Scottish Medical and Surgical Journal*, December, 1907) reports a few cases in which he has tried Calmette's ophthalmo-reaction to tuberculin, a diagnostic test to which there have not been as yet many references in English. The test is extremely simple. If a drop of a 1 per cent watery solution of tuberculin is placed in the eye of a tuberculous patient, a definite reaction ensues. Within a few hours there is a congestion of the conjunctiva, which soon passes into definite conjunctivitis. The pupil also becomes dilated. The reaction is at a maximum in 12 hours, and has completely disappeared in a couple of days. The inconvenience to the patient is trifling. No reaction occurs in the eye of a non-tuberculous patient. In the carrying out of the test ordinary tuberculin should not be used, as it is usually suspended in glycerine, which may interfere with the accuracy of the test by irritating the conjunctiva. Calmette advises a preparation of dry tuberculin, which can be dissolved in distilled water before use. He claims that the reaction has a high diagnostic value, and his results have been supported by other observers, including Boyd. If the method should stand the test of time, it will be of great help in diagnosis, as it furnishes an easy method of recognising obscure tuberculous lesions. R.

Fat Embolism.—While fat embolism is only in rare instances a cause of death, it is in itself a frequent occurrence. Graham (*Journal of Medical Research*, July, 1907) publishes the history of a fatal case, and gives a critical summary of the literature of the subject. He concludes: (1) Two lesion complexes may be found in fatal cases of fat embolism. The first consists of an extreme blocking of the pulmonary vessels, together with less marked involvement of those of the heart. There is only a negligible blocking of the vessels of the general circulatory system. The second involves widespread embolism of the vessels, and the pulmonary lesion is overshadowed by lesions of the heart, kidney, and central nervous system. (2) Death occurs in the first class of cases from asphyxia, and follows closely upon the trauma or disease leading to the entrance of fat into the vessels. In the second class of cases it depends upon multiple cerebral emboli, associated with embolism and fatty degeneration of the heart. In such cases death follows only after the lapse of some days. (3) The dividing line between fatal and non-fatal amounts of fat is ill-defined, and individual susceptibility seems to vary. (4) An amount of fat, which would be fatal if suddenly gaining entrance into the blood stream, produces no unfavourable symptoms if it enters the circulation in divided doses separated by intervals of several days. Such fat is gradually eliminated through the kidneys and by the phagocytic action of the leucocytes. (5) Fatty degeneration of the heart in fatal cases is often accompanied by similar changes in the diaphragm, the skeletal muscles remaining unaffected. These diaphragmatic changes may in part account for the respiratory disturbance always observed. R.

Tuberculin Treatment in Children. — Riviere (*British Medical Journal*, October 26, 1907) publishes the results of his experiences of tuberculin treatment in children. As vaccine treatment in general has hardly yet received the support it deserves, we call attention to his paper. Riviere is, on the whole, a disciple of Wright's, and he hardly ventures on any independent criticism. He believes that during treatment the opsonic index should be carefully watched, though he permits treatment without opsonic control where the latter is impracticable. The all-important point as regards success of treatment is dosage, and the discouraging results obtained by some observers have been due to over-dosage. In Riviere's own experience he finds 1-12,000 to 1-8,000 mg. a suitable dose for a child of one year, 1-4,000 mg. for a child of five years, and 1-3,000 for a child of 10 or 12 years. With regard to localised tuberculosis, he finds tuberculin, "in suitable doses, an almost certain remedy." The improvement following on treatment is shown not only by local healing, but by improvement in general health, bodily and mental. Among the cases treated were dactylitis, superficial abscess, tuberculous glands and joints. General tuberculosis should, in Riviere's opinion, also be treated by tuberculin. The opsonic index is thereby steadied, and the general symptoms alleviated. He makes reference specially to phthisis and tuberculous peritonitis. The condition he regards as most unpromising for success is marked wasting. Riviere also believes that the injection of tuberculin in some way gives protection against secondary infections. The opsonic index to other organisms seems to bear a certain parallelism to the tuberculo-opsonic index. Riviere closes with a strong plea for a wider use of tuberculin. R.

The Anæmia of Ankylostomiasis.—Boycott (*British Medical Journal*, November 9th, 1907) describes the points of contrast between the anæmia of ankylostomiasis and idiopathic pernicious anæmia. (1) As regards the histology of the blood-film in pernicious anæmia, many of the cells are large and contain much hæmoglobin, whereas in ankylostomiasis the majority of the cells are small, and contain a small quantity of hæmoglobin. In other words, the colour index of pernicious anæmia is high, that of ankylostomiasis low. Moreover, the more severe the anæmia, the greater the contrast on this point. (2) As regards the volume of blood and its oxygen-bearing capacity, the contrast is equally marked. In ankylostomiasis the volume of blood is nearly twice the normal, and therefore, although the hæmoglobin percentage is only 45 per cent. of the normal, the total oxygen capacity is hardly diminished at all. In pernicious anæmia, on the other hand, there is a real diminution in the total quantity of hæmoglobin in the body, and therefore in the oxygen-bearing capacity of the blood. In severe cases the oxygen-bearing capacity is reduced by a half. R.

Pelvic Inflammation in the Female.—Wilson (*Journal of Obstetrics and Gynæcology*, July, 1907), in the course of a general paper on pelvis inflammation, gives some bacteriological findings of interest. In the case of twelve recent puerperal infections, micro-organisms were found in every case, the distributions being as follows:—Streptococci alone, 4; streptococci with staphylococcus aureus, 2; streptococcus with other organisms, 4; other organisms, 2. It is not so stated, but we gather that the cases referred to were examined on the post-mortem or operation table, and were therefore cases of great severity; hence the high proportion of streptococcal infections. In 43 cases of sub-acute or chronic suppurative pelvic inflammation, no germs were found in 10 cases; in 10 streptococcus was found alone; and in association with other germs in 5; staphylococcus aureus was found in 2; staphylococcus albus in 1; and mixed staphylococci and pneumococci in 1; bacillus coli was found in 1. With regard to pyosalpinx, of 13 cases examined, 4 were found to be sterile; 1 contained streptococcus, 1 staphylococcus albus; 1 staphylococcus and pneumococcus; 1 gonococcus; and 5 various saprophytes. R.

The Cancer Problem.—Skerrett (*British Medical Journal*, November 2nd, 1907) makes an ingenious suggestion bearing on the nature and treatment of cancer.

Starting with the facts that the essential characteristic of the cancer cell is its apparently unlimited power of reproduction, and that reproduction is governed by the cell-nucleus, he asks whether it is possible so to act on the nucleus as to inhibit this power of excessive reproduction. He then refers to the observation that acute inflammations seem to exert a retrogressive influence on cancerous growths. He suggests that it is possible that the pabulum for the excessive nuclear growth in cancer is supplied by an influx of leucocytes to the part, and that the effect of inflammation is to starve the tumour by depriving it of its leucocytic supply. Would it then be possible, he asks, to modify nuclear growth by diminishing in the food the supply of the materials necessary for the formation of nuclein—or so to act on nuclein as to alter its functional activity? In reply to the latter question he suggests the possibility of supplying arsenic with the food, so that the nuclein molecule might possibly take up that metal instead of phosphorus, and thereby undergo some change in its functional activity. He suggests, therefore, that the results of taking a nuclein-free diet while arsenic is administered internally should be observed. R.

MEDICAL NEWS IN BRIEF.

Contamination of Town Milk.

Dr. G. Trew Cattell, one of the medical officers of health for Berkshire, has just issued a report dealing with his inspection this year of the dairies and milkshops. In taking samples of milk fresh from the cow, and kept in a covered vessel for a certain period of time, and also taking samples which had been exposed in large open porcelain bowls for a like period to the ordinary conditions prevailing in the main street of a town, he found the number of micro-organisms from the one so exposed to be enormously increased as compared with the covered sample. The dust of the streets of a town was mixed largely with the dried excreta of animals and human expectoration, and very frequently contained germs of disease. The bacilli of scarlet fever, of tuberculosis, and of enteric fever specially throve in milk. It was quite possible that many epidemics of the former disease which had begun in a mysterious manner and whose cause had never been accurately determined, might be traced to the accidental contamination of the milk supply in the manner indicated. The habit which consumptive people had of constantly expectorating—a habit which, from the nature of their disease, it was difficult to prevent—constituted a serious danger. The sputum, generally swarming with tuberculous bacilli, quickly became dried on the pavement or roadway, and was blown about in the form of dust, and, should this settle on the milk, there was a grave possibility of children being brought into contact with tuberculous infection, to which they were peculiarly susceptible. He suggested that greater care was necessary in the way that milk was handled before sale, and that it should never be allowed to be exposed in uncovered vessels. It would, he added, be an advantage if all authorities in the county adopted one set of regulations, thus securing unanimity of action.

Teaching of Midwifery in Ireland.

A meeting of Masters, Assistant Masters, and ex-Assistant Masters of the Dublin Maternity Hospitals was held in the Royal College of Physicians, Dr. Hastings Tweedy, Master of the Rotunda Hospital, in the chair. The following resolution was proposed by Dr. R. D. Purefoy, ex-Master of the Rotunda Hospital, and seconded by Dr. Gibson, Master of the Coombe Hospital, and passed unanimously:—'That this meeting, consisting of the Masters and Assistants, past and present, of the Dublin Maternity Hospitals, is unanimously of opinion that the proposed shortening of the course in practical obstetrics from six to three months would seriously interfere with the work of the maternity hospitals; that it would increase, rather than lessen, the difficulties in providing each student with the required number of cases; and that, at the same time, it would materially diminsh his opportunities of obtaining practical instruction." It was then proposed by Sir William Smyly, ex-Master of the Rotunda Hospital, seconded by Dr. A. J. Horne, Master of the National Lying-In Hospital, and passed unanimously:—"That, in the opinion of this meeting, it is most desirable that the recommendations of the General Medical Council with regard to a Clinical and Practical Examination in Obstetrics and Gynæcology, be adopted, especially as the meeting has been assured that the Masters of the Maternity Hospitals will further the scheme by every means in their power."

Infantile Mortality in Poplar.

In reporting upon the desirability of appointing a female health visitor in Poplar, the Public Health Committee of the Poplar Borough Council state that last year in the borough 822 infants under one year of age died, and of these 188 were under one month old. The total number of births in the year was 5,363. Upon inquiries at 26 factories in Poplar, where a total of 5,641 women are employed, it was found that 769 were married, or 13.6 per cent. The Local Government Board have asked the Poplar Council what action they propose to take upon the information of births to be received under the Notification of Births Act with a view to the reduction of infant mortality. The Public Health Committee will recommend the Council to agree to the principle of the appointment of a health visitor.

The Coombe Hospital, Dublin.

A special meeting of the directors of the hospital was held on December 17th to elect a Master in place of Dr. Thomas G. Stevens, whose period of office had expired. There was a large attendance of Governors, the Right Hon. the Lord Mayor presiding. The candidates were: Dr. M. J. Gibson, M.A., M.D., B.Ch., B.A.O., Dub. Univ., and Dr. Thomas Neill, B.A., M.B., B.Ch., B.A.O., Dub. Univ., both having occupied the position of Assistant Master in the hospital. A ballot having been taken, the Lord Mayor declared Dr. Gibson elected by 11 votes as against 5 for Dr. Neill. The newly-elected Master was then notified by the Chairman of his election to the responsible position, and Dr. Gibson having thanked the Board for the confidence they had placed in him, the proceedings concluded.

PASS LISTS.

Royal College of Surgeons, Edinburgh.

At a meeting of the College held on the 16th inst., the following gentlemen were elected Fellows:—Bryan Foster, M.B., Ch.B., Melb.; William James France, L.R.C.S.E.; Henry Goodwyn, L.R.C.S.E.; Henry John Lotz, M.R.C.S.Eng., L.R.C.P.Lond., D.P.H. Camb.; Raymond Herbert Price, M.B., C.M.Edin.; John Fordyce Robertson, M.D.Edin.; Cyril Shellshear, M.B., C.M.Syd.; Fred Stoker, M.B., Ch.B.Durh.; Herbert Pank Thompson, M.D.Edin.; Walter Woodword White, M.D.; C. M. McGill, L.R.C.S.E.; David Percival Dalbreck Wilkie, M.B., Ch.B.Edin.; and James Wilson, M.B., Ch.B.Aberd.

Apothecaries' Hall, London

The Society of the Apothecaries of London has granted the L.S.A. Diploma to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—R. Beesley and E. S. Cooke.

The Salford Board of Guardians recently decided that public vaccinators should receive half-a-crown for each case of successful primary vaccination and re-vaccination performed by them at the surgery, and that the fee for each case after the twenty-ninth should be one-and-sixpence.

The *Daily Mail Year Book* having now attained the eighth year of its existence, has become more or less familiar to readers. It contains the usual vast storehouse of information of a manifold kind. One interesting feature is the brief biographies of men and women of our time. The price of this 1908 compendium of reference for the writing desk is only sixpence.

NOTICES TO CORRESPONDENTS, &c.

☛ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

EASTERN.—The Siamese certainly are going ahead, and have a good appreciation of European medicine. As the result of a visit recently paid by the King of Siam to the Virchow Hospital in Berlin, a contract has been placed for the whole equipment of a similar hospital for the city of Bangkok. The building materials are to a large extent to be shipped from Germany, and there will be an installation of apparatus, not only for carrying out operations in major surgery, but also for bacteriological work. An ambulance department has already been inaugurated in the Siamese defensive services, the Geneva Red Cross being adopted with a vernacular emblem, and the King of Siam is desirous of conferring upon his subjects the full advantages of modern progress. The sum to be expended, including buildings and the expenses of the staff, cannot be less than £25,000.

THE INDEX FOR 1907.

The Index for the present volume, of which this number is the last, will appear in our next week's issue.

MR. J. WATSON.—The question of priority in the discovery of the infection of Malta Fever is fully discussed in our issue for November 6th, 1907, page 510.

THE NEW TREATMENT.

Away with judge and jury, pray!
For court and gaol have had their day,
  No more shall laws control us;
We shall, immune, from every ill,
Cure murderers by a little pill
  And burglars by a bolus.

If draughts, not of the sort he likes,
Effect no cure in Mr. Sikes,
  Then careless what 'twill cost us,
Our stern prescription, I profess,
Shall, while we look for swift success,
  Be "Repetatur haustus!"

If he, however, grow and grow
In crime and vicious habits, though
  To virtue we still urge on,
Aware what treatment best befits
His fell disease, we'll call for its
  Removal by the surgeon.

Our grateful praise then, I insist,
Is what the skilled pathlologist
Shall—what reward's like that?—earn,
  For soon "the mixture as before"
Shall make our gaol-birds more and more
  To all mankind a pattern.

M. S.

—*Daily Chronicle.*

WESTRALIAN.—There are several Post-Graduate centres in London, offering various facilities for study. Apply to the Dean of the West London Post-Graduate College, Hammersmith Road, W., or to the North-East London Post-Graduate College, Prince of Wales's Hospital.

SUBSCRIBER, M.D.—We have carefully considered the matter and laid the facts—impersonally, of course—before a member of the profession, who is well acquainted with such problems. His advice, in which we concur, is that you would do well not to accept such an appointment under present circumstances. The advantages that might accrue would be more than counterbalanced by the risks involved.

Appointments.

DEVANE, J. F., M.B., B.Ch., D.P.H., House Surgeon at the County Infirmary, Limerick.

GUNNING, C. J. H., M.R.C.S., L.R.C.P.Lond., Clinical Assistant to the Ophthalmic Department at St. George's Hospital.

HAWTHORNE, C. O., M.D.Glasg., M.R.C.P.Lond., Examiner in Medicine and Clinical Medicine in the University of Glasgow.

MORRISON, J. T. J., M.B.Cantab., F.R.C.S.Eng., Examiner in Medical Jurisprudence at the University of Glasgow.

NICOL, J. H., M.B., M.S.Glasg., Examiner in Surgery at the University of Glasgow.

ROBB, D. M., M.B., Ch.B.Edin., Senior House Surgeon at the Clayton Hospital, Wakefield.

SLOAN, SAMUEL, M.D., M.S.Glasg., Examiner in Midwifery at the University of Glasgow.

Vacancies.

St. George's Union.—Second Assistant Medical Officer at their Infirmary, Fulham Road, West Brompton, S.W. Salary, £120 per annum, with board, residence, and washing. Applications to the Medical Superintendent.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—A Casualty Medical Officer. Salary, £200 per annum, with lunch. Applications to Stewart Jones, Secretary. (See Advert.)

Parish of Bermondsey Infirmary.—First Assistant Medical Officer. Salary, £170 per annum, with rations, washing, furnished apartments, and attendance. Applications to E. Pitts Fenton, Clerk, 283, Tooley Street, S.E.

University of Sheffield.—Demonstrator in Anatomy. Salary, £150 per annum. Applications to W. M. Gibbons, Registrar.

Birmingham City Asylum.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Huddersfield Infirmary.—Male House Surgeon. Salary, £100 per annum, with board, residence, and washing. Applications to Mr. J. Bate, Secretary, Infirmary, Sheffield.

CLEFT PALATE AND HARE-LIP:

The Earlier Operations on the Palate.

BY EDMUND OWEN, M.B., F.R.C.S.,

Consulting Surgeon, St. Mary's Hospital, and to the Hospital for Sick Children, Great Ormond Street, London.

Pp. 111, with 32 Illustrations. Just published.

Price, 2s. 6d. net.

"*The most favourabe time in life for operating on a cleft palate is between the age of two weeks and three months.*" (Page 41.)

London: BAILLIERE, TINDALL & COX.

BY THE SAME AUTHOR:

SURGICAL DISEASES OF CHILDREN.

Third Edition, Revised and Enlarged.

Pp. 504, with 5 Chromo-lithographs and 120 Engravings.

London: CASSELL & Co., LTD.

SECOND EDITION, with Illustrations, royal 8vo, 10s. 6d.

The Treatment of Lateral Curvature OF THE SPINE.

By BERNARD ROTH, F.R.C.S.

"In speaking of the first edition we expressed the hope that this book would do something to check the unscientific and often disastrous treatment of lateral curvature of the spine by spinal supports and prolonged rest, and this new edition is even better calculated to show the good results which may be obtained in lateral curvature by posture and exercise."—LANCET.

"There can be no doubt that good work has been done by the author by his strong advocacy of the more rational method of treating lateral curvature of the spine by exercises."—BRITISH MEDICAL JOURNAL.

London: H. K. Lewis, 136 Gower Street, W.C.

NOW READY. SIXTH EDITION, 587 pages, with 249 Illustrations. Royal 8vo. Price 15s. net.

Diseases and Injuries of the Eye,

WITH THEIR MEDICAL AND SURGICAL TREATMENT.

By GEORGE LAWSON, F.R.C.S.

Revised and Re-written by ARNOLD LAWSON, F.R.C.S.

NOW READY, with Photograph and numerous Illustrations.

Third Edition enlarged. Price 10s.

ON DISEASES OF THE EYE.

By CHARLES BELL TAYLOR, F.R.C.S., and M.D.Edin.

Fellow Medical Society, London; late President of the Parisian Medical Society; Surgeon Nottingham and Midland Eye Infirmary.

London: Kegan Paul, Trench & Co., Paternoster Square.

By W. ARBUTHNOT LANE, M.S.

Cleft Palate and Hare Lip.

New Edition, in large clear type, demy 4to, 5s.

"Mr. Lane makes out a clear case for early and almost immediate operation. To sum up: Mr. Lane has absolutely proved his contention, and rendered it quite clear that early operation is the right course on every ground, developmental and otherwise; and, further, that delay in performing staphylorrhaphy until the third or sixth year is fraught with most harmful results, and should not be permitted."—*British Medical Journal*, Jan. 27th, 1906.

Operative Treatment of Fractures.

New Edition, uniform with above, 7s. 6d.

The Operative Treatment of Chronic Constipation.

New Edition, uniform with above, 2s. 6d.

HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hæmoglobin
with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

☞ Extremely useful in **Rickets, Scrofula, General Debility, Anæmia, Weak Heart, Neurasthenia,** and Convalescence from illness such as **Pneumonia** or **Influenza.**

☞ Unsurpassed as a **Strengthening Restorative in Diseases of the Lungs.** Has a very agreeable taste, and is taken with the utmost relish even by Children.

FREE FROM BACTERIAL GROWTH. UNCHANGED BY KEEPING.

These important qualities are guaranteed by using the highest permissible temperature in the process of manufacture (130° to 140° Fahr. for 24 hours). No guarantee of this description is possible for preparations made by a cold process with ether.

☞ **In prescribing, always state "HOMMEL'S" Hæmatogen as spurious imitations are offered.** ☜

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - - Take from Half to One Teaspoonful twice a day in milk.
Children - „ One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid.
Adults - - „ One Tablespoonful twice a day **before** the two principal meals.

☞ **SAMPLES AND LITERATURE,** *gratis and carriage paid, on application.*

Valentine's Meat-Juice

IN PNEUMONIA, PHTHISIS AND INFLUENZA.

"The Food Par Excellence For a Tired Stomach."

Where a powerful and energetic nourishment is required in a concentrated, rapidly assimilated form, easily administered and readily tolerated, when other forms of food fail, Valentine's Meat-Juice is employed by well known practitioners throughout the world.

Prof. Dr. M. Litten, *Lecturer on Internal Medicine, University of Berlin, and Director of the City Hospital, Berlin, Germany.* "I have employed Valentine's Meat-Juice with patients suffering from Tuberculosis and observed excellent results from its use. I have also used it with good results in the treatment of patients with Anaemia, as well as those convalescent from acute diseases."

O. B. Douglas, M. D., *Ex-President Medical Society, County of New York; Professor Diseases of Nose and Throat; New York Post-Graduate Medical School and Hospital.* "I have been ill with Influenza and used Valentine's Meat-Juice when nothing else seemed to be relished. I consider this an assurance of my confidence in it."

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

Doctors Should Know

that OXO is made by the original Liebig Company, the firm who first introduced concentrated meat foods to the world. They have their own vast cattle farms exceeding one million acres in extent, carrying fine pure-bred British Hereford stock from His Majesty's farms at Windsor and other British breeders. It is the possession of these farms, and the consequent complete control of raw material, that makes the Liebig Company superior to all other manufacturers. OXO is made from cattle certified to be free from tuberculosis; it is standardised, pure, free from preservatives, and untouched by hand.

THE TUBERCULOSIS PROBLEM.

Given the Sociological Conditions of Sanatoria and Medico-Dietetic Conditions of "MIOL," there is evidence arriving daily from medical men that MIOL will satisfactorily combat tubercular Disease.

"Miol"

"MIOL" IN PULMONARY DISEASE—The air passages are relieved from the obstructive morbid secretions; breathing is soon restored to the normal. Hæmoptysis is at once arrested, night sweats stop in about three days, the irritating cough is speedily removed.

The foul-smelling septic condition is corrected by the antiseptic action of the contained free Iodine, and the whole series of morbid symptoms are removed.

"MIOL" is a nutritive tonic and stimulant promoting the functional activity of all the organs of the body as well as being the most active digestive of its kind known to Science.

MOST PALATABLE. **CHILDREN LIKE IT.**

"MIOL" is being rapidly established in all the principal Hospitals and Sanatoria.

Send for booklet and sample with actual Clinical Reports obtained by Medical Men from Patients.

Will the Doctor kindly—

(1) Weigh each case before taking "MIOL," and each fortnight afterwards?

(2) Examine the sputa and blood before and after taking "MIOL" for Tubercle Bacilli?

(3) Note temperature, sweating, appetite and digestion before and after beginning "MIOL" from time to time?

Samples and Clinical Reports on application.

LITERATURE AND SAMPLES FREE TO MEDICAL MEN.

IN THE TREATMENT OF

ANÆMIA, NEURASTHENIA, BRONCHITIS, INFLUENZA, PULMONARY TUBERCULOSIS, AND WASTING DISEASES OF CHILDHOOD, AND DURING CONVALESCENCE FROM EXHAUSTING DISEASES,

THE PHYSICIAN OF MANY YEARS' EXPERIENCE

KNOWS THAT, TO OBTAIN IMMEDIATE RESULTS, THERE IS NO REMEDY THAT POSSESSES THE POWER TO ALTER DISORDERED FUNCTIONS LIKE

"Fellows' Syrup of Hypophosphites."

MANY A TEXT-BOOK ON RESPIRATORY DISEASES SPECIFICALLY MENTIONS THIS PREPARATION AS BEING OF STERLING WORTH.

TRY IT, AND PROVE THESE FACTS.

SPECIAL NOTE.—Fellows' Syrup is never sold in bulk, but is dispensed in bottles containing 8 oz. and 15 oz.

THIS PREPARATION MAY BE OBTAINED AT ALL CHEMISTS AND PHARMACISTS THROUGHOUT THE UNITED KINGDOM.

"Formolyptol"

ITS

BACTERIOLOGY

The crucial test of the efficacy of an antiseptic fluid is the bacteriological one. When we state that FORMOLYPTOL is equal in germicidal potency to a 1-1000 solution of Corrosive Sublimate, without the irritant or toxic properties of the latter drug, we base our claim upon the results of careful laboratory experimentation with the different varieties of germ life. Complete and conclusive reports from prominent bacteriologists sent upon request.

ANDRUS & ANDRUS

THE TASTELESS AND BEST NATURAL APERIENT

ANALYSIS

Of the ÆSCULAP SPRING, BUDAPEST.
By Prof. JOHANN MOLNAR, Government Analyst.

SALTS IN 10,000 PARTS OF WATER.

Sulphate of Potassium	0·104
Sulphate of Ammonia	0·061
Sulphate of Sodium	139·063
Sulphate of Magnesium	172.805
Sulphate of Calcium	20·788
Chloride of Sodium	29·047
Carbonate of Sodium	9·969
Carbonate of Iron	0·097
Carbonate of Manganese	0·429
Alumina	0·349
Silicic Acid	0·092
Total	372·894

"Contains the Sulphates of Magnesium and Sodium in unusually large quantities. It is an admirable aperient water."—THE LANCET.

"ÆSCULAP is the clearest and purest of all the Hungarian Aperient Waters."—THE HOSPITAL.

"Of uniform strength and free from organic impurity."—EDINBURGH MEDICAL JOURNAL.

"A valuable remedial agent in stomach and intestinal affections."—GLASGOW MEDICAL JOURNAL.

"It is an efficient aperient."—DUBLIN JOURNAL OF MEDICAL SCIENCE.

"It possesses the decided advantage of being less unpleasant to take than many other bitter waters, as well as being free from any organic impurity."—THE MEDICAL PRESS.

ÆSCULAP

May be obtained from all Chemists, Druggists, Shippers, and Mineral Water Dealers.

THE BOTTLING AND MANAGEMENT OF THE ÆSCULAP SPRINGS, BUDAPEST, ARE CARRIED ON DIRECTLY UNDER ENGLISH SUPERVISION.

THE ÆSCULAP BITTER WATER CO., LTD., LONDON, E.C.; AND BUDAPEST.

In all disorders of the respiratory tract in which inflammation or cough is a conspicuous factor, incomparably beneficial results can be secured by the administration of

Glyco-Heroin (Smith)

The preparation instantly diminishes cough, augments expulsion of secretions, dispels oppressive sense of suffocation, restores regular, pain-free respiration and subdues inflammation of the air passages.

The marked analgesic, antispasmodic, balsamic, expectorant, mucus-modifying and inflammation-allaying properties of GLYCO-HEROIN (SMITH) explain the curative action of the Preparation in the treatment of

Coughs, Bronchitis, Pneumonia, Laryngitis, Pulmonary Phthisis, Asthma, Whooping Cough

and the various disorders of the breathing passages.

GLYCO-HEROIN (SMITH) is admittedly the ideal heroin product. It is superior to preparations containing codeine or morphine, in that it is vastly more potent and does not beget the bye-effects common to those drugs.

Dose.—*The adult dose is one teaspoonful, repeated every two or three hours. For Children of more than three years of age, the dose is from five to ten drops.*

Samples and exhaustive literature bearing upon the preparation will be sent, post paid, on request

ST. PATRICK'S HOSPITAL FOR MENTAL DISEASES.

THE GOVERNORS OF

ST. PATRICK'S HOSPITAL, DUBLIN

(FOUNDED BY DEAN SWIFT IN 1745),

Wish to announce that they have acquired a large property, in accordance with their Royal Charter (200 acres), and established a Private Asylum in connection with the Hospitals at Lucan, for the reception of patients of both sexes suffering from Mental Disease.

A NEW VILLA has been erected at Lucan for the accommodation of a limited number of gentlemen, and the entire establishment has been lighted by electricity.

The parent institution in Dublin continues its curative work, has undergone almost entire reconstruction, receives both male and female patients, and its recovery rate is very satisfactory. The Governors are anxious that the Medical Profession should be acquainted with the work of this historic institution, which has been devoted for over a century and a half to the reception and curative treatment of the insane of Ireland.

Urgent cases can be admitted by direct application to the Medical Superintendent.

For further particulars, forms of admission, &c., apply to the REGISTRAR, St. Patrick's Hospital, James Street, Dublin.

PRIVATE ASYLUMS,

Co. DUBLIN.

For Patients of the Upper Class suffering from Mental and Nervous Diseases, and the Abuse of Drugs. Established 1825.

HAMPSTEAD,
GLASNEVIN, FOR GENTLEMEN.

HIGHFIELD,
DRUMCONDRA, FOR LADIES.

Telephone No. 1032.

These Hospitals are built on the Villa System, and there are also Cottages on the demesne (154 acres), which is 100 feet above the sea-level, and commands an extensive view of the Dublin Mountains and Bay.

Voluntary Patients admitted without Medical Certificates.

For further information apply for illustrated prospectus, &c., to the Resident Medical Superintendents, Dr. HENRY MARCUS EUSTACE, Highfield, Drumcondra, or Dr. WILLIAM NEILSON EUSTACE, Hampstead, Glasnevin; or at the office, 41 Grafton Street, Dublin. Telephone 198. On Mondays, Wednesdays and Fridays, from 2 to 3 p.m.

THE ONLY ASEPTIC FEEDER MADE IS THE ROTUNDA FEEDING BOTTLE.

It is simple—only a pure rubber teat and bottle—no valve. It safe—for it can be sterilised. It is cheap—6d.

Can be had wholesale from any Druggists' Sundry House, or from

LEONARD & CO., Chemists, Dublin & Belfast.

Leonard's Rotunda Tissue, 1/- per lb.

Leonard's Clinical Thermometers, 1/- each.

STRETTON HOUSE,

Church-Stretton, Shropshire.

A Private HOME for the treatment of Gentlemen suffering from Mental diseases. Bracing hill country. See "Medical Directory," p. 1958.

Apply to Medical Superintendent. Telephone: 10 P.O. Church-Stretton.

THE RETREAT PRIVATE ASYLUM

Near ARMAGH.

(ESTABLISHED 1824.)

Licensed for the reception of ladies and gentlemen of the upper and middle classes suffering from

MENTAL AND NERVOUS DISEASES.

(Voluntary Boarders and Inebriates admitted.) This establishment has lately undergone many structural alterations and improvements, and the walks and grounds are extensive and picturesque.

Great care and attention are bestowed upon the patients, outdoor and indoor games and regular carriage exercise being provided.

Golf links have recently been added.

For further information apply to the Medical Superintendent, Dr. J. GOWER ALLEN, J.P., or Mr. JOSEPH ALLEN, Clonallen, Armagh.

STEWART INSTITUTION

FOR IMBECILE CHILDREN, AND HOSPITAL FOR MENTAL DISEASES, Palmerston, Chapelizod, co. Dublin.

This institution receives imbecile children from all parts of Ireland free, or by partial payment, by election. Full payment cases at moderate rates. One vote for every 10s. 6d. subscribed annually. A life vote for £5 5s. donation.

The Hospital for Mental Diseases—a separate establishment—receives lady and gentleman patients from £50 per annum upwards, according to accommodation required. Management fully up-to-date in all particulars. Beautiful situation. Best modern sanitation. Fine demesne with necessary privacy. Voluntary boarders received.

Resident Medical Superintendent: Dr. F. E. Rainsford. All particulars from Secretary at Office, 40 Molesworth Street, Dublin.

DUBLIN.

FARNHAM HOUSE

For Gentlemen; MARYVILLE for Ladies.

TAMAR INDIEN GRILLON.

A Laxative, Refreshing, and Medicated Fruit Lozenge.

VERY AGREEABLE TO TAKE, AND NEVER CAUSING IRRITATION.

Its physiological action assures the immediate relief and . . . effectual cure of . . . . . . **CONSTIPATION,**

HÆMORRHOIDS, BILE, HEADACHE, LOSS OF APPETITE, AND INTESTINAL OBSTRUCTIONS

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness; and the same dose always produces the same effect— that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with the most marked success.

Wholesale—London: E. GRILLON, 67 Southwark Bridge Road, S.E.

Sold by all Chemists and Druggists, 2s. 6d. a box, stamp included.

SAL HEPATICA

EFFERVESCENT SALINE LAXATIVE.
URIC ACID SOLVENT.

A combination of the Tonic, Alterative and Laxative Salts similar to the celebrated Bitter Waters of Europe, fortified by the addition of Lithia and Sodium Phosphate.

It stimulates the liver, tones intestinal glands, purifies alimentary tract, improves digestion, assimilation, and metabolism.

Especially valuable in **Rheumatism, Gout, Bilious Attacks, Constipation.** Most efficient in eliminating toxic products from intestinal tract or blood, and correcting vicious or impaired functions.

Write for free sample.

"A distinct advance on Easton's Syrup."

The Lancet.

Bynin Amara

BYNIN-AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloidal principle.

As a digestive tonic therefore BYNIN-AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

COMPOSITION

Quinine Phosphate - - -	1½ grains.
Iron Phosphate - - -	2 ,,
Nux Vomica Alkaloids equal to Strychnine - - -	1/16 ,,
Bynin, liquid malt - - -	1 ounce.

DOSE FOR ADULTS.—One table-spoonful suitably diluted.

A Sample Bottle will be sent Free to Medical Men on request.
